In the preceding tables we have stated the number of communicants connected with the principal Protestant missions, so far as we have been able to ascertain them. If we had given also the baptized, the numbers would have been

much greater, and they would have been still further augmented, if to them we had added others under special instruction. Thus, in the missions of the United Brethren the numbers of these several classes in 1856 were as follows :—

¹ United Brethren.

² The schools in the Sandwich Islands are results of the mission, but they are now entirely supported by the Hawaiian Government.

³ These statistics, particularly in the second table, are in various instances incomplete. Where they are so, the numbers given are of course under the truth.

Missions.

Communicants	19,583
Baptized adults	10,607
Baptized children.....	21,245
Candidates for baptism, new people, and excluded.....	19,912
Total.....	71,347

In the missions of the Society for the Propagation of the Gospel in Foreign Parts, these classes in India were as follows:—

Communicants	5,133
Baptized adults and children	19,901
Unbaptized persons under instruction	6,697
Total.....	31,731

In most missions, however, the numbers of the baptized and unbaptized persons connected with them bear a much less proportion to the communicants.

With the view of giving some idea of the expense of such varied and extensive operations, we shall here subjoin a statement of the receipts and expenditure of the principal missionary bodies for one year:—

ENGLISH.	Year.	Receipts.	Expen.

These statements are nearly complete as regards the societies of this country; but they are imperfect regarding those of the continent of Europe and America. We have, however, found about L.380,000 expended in one year on British missions among the heathen; about L.48,000 on continental, including those of the United Brethren, and about L.167,000 on American. The continental and American societies which are not included in the above list, are for the most part inconsiderable; and if we make a moderate allowance on account of them, we shall have an expenditure of about L.600,000 a year by the Protestant churches on missions among the heathen.

It is a fact not unworthy of notice, that of the heathen races who have been brought to receive the gospel, by far the greatest numbers are Negroes and their descendants. In the West Indies, including British and Dutch Guiana, and on the western coast of Africa, the communicants connected with various missions amounted to no fewer than 105,315. In 1843 there were also 128,410 black and coloured people, members of the Methodist Church in the United States, and it is probable the numbers have since that time greatly increased. There were also considerable numbers connected with the Baptist, the Presbyterian, and other churches in that country. We are well aware, indeed, that the instruction which is given to the slaves in the Southern States is in many, perhaps most cases, very defective, and in some shamefully perverted; yet even among them, we doubt not, there may be found many real, though perhaps not very intelligent converts. Taking these several statements into account, we would not be surprised though it should be found, that in the present day there are more real converts from among the Negro race than from among all other heathen nations put together. But be this as it may, the facts we have stated furnish a striking example of the providence of God overruling the wickedness of man for good, seeing it has been through means of the system of slavery, as carried on by men calling themselves Christians, that so many of the Negro race came to have an opportunity of receiving any religious instruction whatever.

Missions and missionaries have been very falsely estimated both by their friends and advocates, and by those who have been hostile or indifferent to them. Such as were opposed to them commonly looked on missionaries as ignorant, weak-minded enthusiasts; while their friends and advocates have no less erred in looking on them as men of more than ordinary piety, zeal, disinterestedness, and devotedness. In engaging in this work, some noble spirits are doubtless animated by what has been emphatically called "a passion for missions," and some by "the romance of missions;" but the generality, there is ground to conclude, make choice of the service on the same principles, and with the same views, as most persons choose their employments in life, and, in a special manner, from the same motives (often very much mixed) as many choose the Christian ministry as their profession. The truth is, missions afford to many an opening in life,—opportunities of rising in the world, or at least of obtaining a position which they might not so readily otherwise obtain. There are, of course, differences among them, corresponding somewhat to the characteristics of the several churches to which they belong; but in general they will not be found superior, as regards piety, zeal, disinterestedness, devotedness, and other moral qualifications, to the better class of ministers in their respective denominations who remain at home. Many people associate ideas of hardships, privations, and sufferings with their picture of missionary life; but in reality, with a few exceptions, missionaries are generally better off, in regard to salaries and the outward accommodations of life, than most of them could have expected to be in their own country. The chief points in regard to which missionaries are often placed in disadvantageous circumstances are, an unhealthy climate, and the difficulties they often have regarding the education and settlement of their children in life.

Intellectually, the character of missionaries has latterly much improved. When missionary societies were formed in England and Scotland, toward the end of the eighteenth century, an idea appeared to prevail, that persons would do well enough as missionaries to the heathen whom no one

¹ By much the larger portion of the funds of the Propagation Society are raised for, and expended on, the English Church in the British Colonies. Of the sum above mentioned, the portion expended on missions among the heathen probably did not exceed one-third.

² Part of this expenditure is on account of missions in Ireland, France, Germany, and in various of our colonies.

Missions. would have thought of for ministers at home. But the standard of the education of missionaries has gradually risen; and a large proportion of those who are now sent out as missionaries are well-educated men, and have for the most part enjoyed a regular training for the ministry. Several of the societies established institutions for the education of missionary students; while numbers who had received the usual education for the ministry, particularly in this country and America, have offered themselves for the service. In the early stage of our missionary societies individual medical men were also sent out, and some even of those who had enjoyed nothing more than a common education were put in the way of receiving some medical instruction before leaving their native country; but latterly, in America especially, a physician has been a very common constituent of a mission; and some years ago a society was established in Edinburgh under the name of the "Medical Missionary Society," which is chiefly under the management of gentlemen of the medical profession in that city, who have shown great interest in the cause.

Missionaries, many imagine, are not much to be relied on as to the accounts which they send home; but we are satisfied that for such suspicions there are no sufficient grounds. There may have been individuals who, giving way to their imaginations, or studying effect in their narrations, or seeking to raise themselves in public estimation, have sent home coloured and exaggerated accounts of their labours, successes, and prospects; but of the general truthfulness of the letters and journals of missionaries we are perfectly satisfied. We may not always form the same judgments as they form of the things related by them, nor be prepared to draw the same conclusions from them; but the simple facts themselves it seldom enters into our minds to question.¹ We cannot, however, say so much for the advocates of missions at home. In printed books, in sermons, and in speeches at public meetings, we frequently meet with coloured, exaggerated, one-sided representations.

Though the success of missions has been considerable, yet it is by no means equal to what is commonly supposed. Of the difficulties in the way of the conversion of the heathen few persons have any adequate idea. To say nothing of the many and powerful moral obstacles, the darkness of the heathen mind is such, that it must generally be exceedingly difficult even to lodge Christian ideas in it,—ideas so foreign and often so opposite to all its previous ideas and its habitual trains of thinking. Nor is the success of missions to be estimated by mere figures. Though the numbers of the baptized, and even of the communicants, in the several missions, and especially in those of particular societies, may appear considerable, yet there can be no question that a large portion of these can be reckoned as converts only in name. Missionaries who exercise much strictness in the admission of members into the church, though the numbers they receive should be comparatively small, are probably more really useful than such as open the door wide, and count their converts by hundreds or by thousands.

Though the following statements have reference to converts from among the Hindus and Africans, they are probably extensively applicable to converts from among heathen nations. Speaking of Hindu converts, Dr Brown remarks:—"Of the general character of the converts we wish we could speak favourably; but it must be acknowledged that even in those missions in which considerable care is exercised in the admission of persons to baptism, it was for the most part very imperfect. Of the sincerity of many

who professed Christianity there was room to doubt; but even those who, it was hoped, were truly converted, laboured under many and great defects."

Missions.

Dr Livingstone gives the following as his impressions of the effects produced on the natives of Africa by missionary labours:—"Many hundreds of both Griquas and Bechuana have become Christians, and partially civilized, through the teaching of English missionaries. My first impressions of the progress made were, that the accounts of the effects of the gospel among them had been too highly coloured. I expected a higher degree of Christian simplicity and purity than exists either among them or among ourselves. I was not anxious for a deeper insight in detecting shams than others; but I expected character such as we imagine the primitive disciples had, and was disappointed. When, however, I passed on to the true heathen, in the countries beyond the sphere of missionary influence, and could compare the people there with the Christian natives, I came to the conclusion that, if the question were examined in the most rigidly severe or scientific way, the change effected by the missionary movement would be considered unquestionably great. We cannot fairly compare these poor people with ourselves, who have an atmosphere of Christianity and enlightened public opinion, the growth of centuries, around us, to influence our deportment; but let any one from the natural and proper point of view behold the public morality of Griqua Town, Kuruman, Likatlong, and other villages, and remember what even London was a century ago, and he must confess that the Christian mode of treating aborigines is incomparably the best.

"The Bechuana mission has been so far successful, that, when coming from the interior, we always felt, on reaching Kuruman, we had returned to civilized life. But I would not give any one to understand by this that they are model Christians,—we cannot claim to be model Christians ourselves,—or even in any degree superior to the members of our own country churches. They are more stingy and greedy than the poor at home; but in many respects the two are exactly alike. On asking an intelligent chief what he thought of them, he replied, 'You white men have no idea of how wicked we are; we know each other better than you. Some feign belief to ingratiate themselves with the missionaries; some profess Christianity because they like the new system which gives so much more importance to the poor, and desire that the old system may pass away; and the rest—a pretty large number—profess because they are really true believers.'"²

It may appear surprising that so many of the converts from heathenism should turn out to be only nominal Christians. It might naturally be thought, that in giving up with the religion of their country and their forefathers, and embracing a new religion of an entirely opposite character, we might calculate on its being the result of inquiry and consideration, and that, if not particularly intelligent, the generality of them would yet be true Christians. But to say nothing of the fact, that in all countries and in all ages (unless, perhaps, in apostolic times) the great majority of professed Christians have been Christians only in name, there are circumstances which, especially in some countries, will account for the natives coming over to the religion of the missionaries, without there being any substantial or spiritual change in their own state and character. Nowhere in modern times have missions been considered as achieving such great and glorious triumphs as in the South Sea Islands; yet, while we have no doubt that much good was in various ways effected in these islands, it yet appears

¹ In making these observations, it must not be imagined that we mean to detract from the intellectual character of missionaries. Among them there are men of highly respectable talents and acquirements, and taking them generally, they will be found to possess a fair average measure of ability and sound-headedness. We have, for the most part, a great respect for their judgment; only we are not disposed to receive it implicitly, just as we are not disposed to receive implicitly the judgments of any other class of men on other subjects.

² Livingstone's *Travels in South Africa*, pp. 107 and 109.

Missions.

that the religious revolution which took place in many of them was materially the result of the example and influence of the chiefs,—more, in the first instance, than of the teaching of the missionaries. So long as the chiefs adhered to the religion of their fathers, the people had no thought of changing it; but as soon as they declared in favour of the new religion, their subjects were ready to follow them. They would now destroy their *morais*, burn or deliver up their idols, profess to be Christians, erect places of worship, observe the Sabbath-day with great outward strictness, while yet they continued to indulge in the most degrading vices, living like the beasts of the field. As regards the great body of the people, the revolution wanted not only purity, but reality. Christianity now became in a manner the national religion, and the mass of the population outwardly conformed to it. It is also worthy of mention that, among the Sandwich Islanders at least, it was a great object of ambition to be received as members of the church. “A *tabu* meeting (*i.e.*, a meeting consisting of selected persons) was to the mind of a Hawaiian one of the most desirable things on earth. Hence the constant pressure by them at the door of the church. It would have been the easiest thing imaginable to have added as many to it in one day as the Apostles did on the day of Pentecost.” Among the Hottentots it was also observed there was a great anxiety to be received as members of the church. We have already seen that the numbers of communicants of the Negro race are very great as compared with other classes of heathens; and though we do not recollect ever to have seen it stated as a fact, yet we greatly suspect that pride is often at the bottom of their desire to be baptized,—that their being so raises them in their own estimation above their unbaptized countrymen, and brings them a step nearer to White men, to whom, though often their oppressors, they cannot help looking up as their superiors. These circumstances, and in some cases self-interest in one form or another, will explain how professed converts from among the heathen are so often only nominal Christians.

The earlier missions of our societies were directed chiefly to uncivilized tribes; and it was strongly argued by many who were opposed to the whole scheme, that civilization must of necessity precede Christianization, and that it was vain to think to communicate the sublime principles of the gospel to barbarians and savages. But the promoters of missions had then scarcely access to civilized nations (India and China, for example, were in a manner closed against them), and unless they sent to barbarous tribes, they could scarcely send forth missions at all. But they had a still further answer to the objection, namely, that the gospel was adapted to, and intended for, all mankind, whether civilized or uncivilized,—“to the Jew and the Greek, the barbarian and the Scythian, the bond and the free.” This answer was no doubt well founded; but it is not unworthy of remark, that what might then perhaps be deemed only theory has since that time been completely established by numerous, varied, and undoubted experiments. Numerous missions have been established in North America among various tribes of the Indians; in the islands of the Pacific Ocean,—the Society, the Hervey, the Navigator, the Friendly, the Fiji, and the Sandwich Islands, and also in New Zealand; among the Negroes in the West India Islands and on the Western coast of Africa; and in South Africa, among the Hottentots, the Griquas, the Bechuanas, the Kafirs, and the Zulus. Numerous missions have also been established among civilized or demi-civilized nations, as in the East Indies, in Burmah, in Siam, and in China. Now, though we may not be able to state with anything like exactness the comparative amount of labour bestowed on civilized and uncivilized countries, nor yet the comparative extent of success in the one and the other, yet it will be seen from the preceding statistics that great numbers

Missions.

from among barbarous tribes have been brought to profess themselves Christians through the labours of missionaries, and there is ground to hope that among them there have been many who have been brought to something more than a mere profession of Christianity,—have, in fact, been genuine believers in Christ. The number of both these classes among uncivilized nations is even greater than among the civilized nations of the East, in India, Burmah, Siam, and China.

It would, however, be a grievous mistake to conclude from this that uncivilized countries are to be preferred as fields of missions to civilized countries, and that the prospects of success are greater among barbarous and savage tribes than among more cultivated nations. Though the statement of the opponents of missions, as to the necessity of civilization in order to Christianization, possessed no weight as an objection, there was great weight in it as a *consideration*, involving important truth, which was deserving of much more attention than it has received to this day,—the connection between civilization and Christianization, and their mutual influence and bearing upon each other. “Christianity and barbarism are certainly not incompatible with each other, yet they are antagonist principles. They may exist together, but they cannot flourish together. Barbarous and savage tribes are generally inconsiderable as regards population, and are often widely scattered and commonly migratory. Their language, from its imperfection and poverty, is ordinarily little fitted for expressing the truths of religion, or, indeed, any idea beyond their daily and immediate wants. It is also commonly unwritten, and they are without books and mental culture of any kind. The untrained and unthinking minds of savages are for the most part less able than educated minds, even supposing them to be inclined, to give continued attention to instruction, and are less capable of understanding, remembering, and applying the instruction given them. If any of them are brought under the influence of religion, their piety partakes of their degraded character and low condition, and there is little prospect of raising up among them a well-qualified native agency to carry on the good work among their countrymen, or among neighbouring tribes and nations. The advantages to which we have alluded are to be found only among nations somewhat advanced in civilization, and in its ordinary accompaniments, education and literature. It is a remarkable and not uninteresting fact, that Judea, the point from which Christianity originally emanated, was the very centre of the then civilized world, and that the countries in which it was at first chiefly propagated, so far as appears from the New Testament and other authentic records, were the countries in which civilization, education, and literature principally prevailed.”

It is not unworthy of remark, that while considerable numbers of pagans have been brought to embrace Christianity, there have been very few Mohammedan converts. This is no doubt partly accounted for by the fact, that where the ruling power is Mohammedan, it is death for any one to renounce the faith of the prophet and to embrace another religion; and with death thus staring them in the face, we need scarcely wonder that few or none should embrace the gospel. But in countries where the ancient churches are still in existence—Turkey for example—there are other and powerful obstacles besides these to the conversion of the Mohammedan population, arising out of the character of these churches. The Mohammedans in the Levant sustain a better character than the Christians. The universal testimony of the Franks is, that there is more honesty, more fair dealing, and more punctuality to engagements among the Turks than among the Christian sects. “It may even be fairly made a question, whether Mohammedanism is not a better religion than the Christianity of the East, from which they naturally take their ideas of what Christianity

Missions. is. Assuredly it is in various respects a less absurd religion. The form in which it is daily presented to them is as a system of idolatrous worship, of gross superstition, of senseless rites and ceremonies, of absolute and pure mummery; while both priests and people are, in point of morals, generally much below themselves. They have thus exhibited before their eyes very natural and very plausible reasons for rejecting Christianity; and it is no wonder that these objections should carry entire conviction to their minds, and lead them to think any further inquiry in regard to it perfectly unnecessary." But even in those countries where the government is not Mohammedan,—India for example,—the Mussulman part of the population are much more opposed to Christianity than the Hindu. They at once despise and hate it. We accordingly find comparatively few converts among the Mohammedans even in India.

Missionary societies have not confined their labours to heathen nations. Several of them have also established missions among the members of the ancient churches, as among the Greeks, the Armenians in Turkey, the Copts in Egypt, the Abyssinians, the Syrians, and other sects in the mountains of Lebanon, the Nestorians in Persia, and the Christians of St Thomas, on the coast of Malabar. It is not unworthy of notice, that these societies, though differing essentially from each other in their character and views on other subjects, wonderfully agreed in the principles on which they proposed to carry on their missions among the ancient churches. The grand object which they had in view was to introduce and diffuse Scripture truth among them, and thereby to revive spiritual life among them, in the hope of effecting their reformation through the instrumentality of their own members: they repudiated the idea of drawing converts out of them, or forming them into separate churches. But after the several societies had prosecuted this scheme for many years, they came, one after another, to the conclusion that it had entirely failed of its great object, and that the only way to deal with these churches was to receive the converts from them and to unite them with their own churches, just as they would do with heathen or Mohammedan converts. The result of such experiments might, we think, have been easily foreseen, and having now been fully tried, we trust they will not be again repeated.

"It is a remarkable fact, how generally missionaries in various parts of the world, and among diverse tribes and nations, bear testimony to the equality of the acquiring faculties of the children in the schools with that of European children. We could adduce testimonies to this effect regarding the Greenlanders, the North American Indians, the Negroes in the West Indies, the South Sea Islanders, and even the savages of New Holland. Nor do we recollect of ever meeting with a single testimony of a contrary nature. It may therefore be considered as an established fact, that whatever differences there may be in the original intellectual capacity of individuals, there is no material difference in the original intellectual capacities of tribes and nations, so far as the *learning* faculties are concerned, at least in regard to the more common branches of education, with the exception, perhaps, of arithmetic. Whether their original powers of reasoning, of imagination, of invention, are equal, is another question. On that point we have not sufficient evidence to enable us to form an opinion."

Missionaries have contributed largely to the science of philology. They have drawn up grammars, vocabularies, and dictionaries of numerous languages, most of them never before reduced to writing, or little known to scholars; and they have made translations of the Holy Scriptures, in whole or in part, and also of other books, into many of them. Many of these works are probably not very well executed, their authors not having been previously much engaged in the study of languages; but others of them, we doubt not,

are scholar-like productions; and the whole cannot but be held a valuable contribution to philological science. In the oriental languages missionaries have particularly distinguished themselves; there are, in fact, few men to whom oriental literature is under such great obligations as to the missionaries in the East.

It is also worthy of notice into how many countries the printing-press has been introduced by means of missions. As regards the extension of the press to new countries, and its application to new languages, there is no class of men to whom mankind are under such obligations as to the missionaries of modern times. India itself is deeply indebted to them, particularly to the Baptist missionaries, who, though they were not the first to employ the press in that country in printing the oriental languages, contributed greatly to its extension and improvement. This powerful engine in diffusing opinions is now in extensive use by the natives themselves, and is employed by them in defence of Hinduism, Mohammedanism, and Parseeism, and in attacks on Christianity itself. The weapons of the missionary are thus turned against himself.

These statements refer exclusively to Protestant missions; but before we close we shall make some brief references to the missions of the Roman Catholic Church. She entered on the work earlier than the Protestant churches, and has prosecuted it for a much longer period. Having at the Reformation lost much ground in Europe, she sought to retrieve her losses by extending her power in other quarters of the world. In this service the Franciscans, Dominicans, and Capuchins, but especially the Jesuits, particularly distinguished themselves. They established missions in India, in Siam, in China, in Japan, and in some of the East India Islands; in Abyssinia, on the Western coast of Africa, in Canada, in Louisiana, in Paraguay, and many other parts of the world; and brought great numbers of the inhabitants of these countries within the pale of the Romish Church. But in the course of the eighteenth century the Catholic missions greatly declined; their pecuniary resources were materially dried up; the missionaries died, and no successors were found for them; and the consequence was, that many of them fell into a state of decay. (*Annals of the Propagation of the Faith*, vol. v., p. 134.)

But in 1822 an "Institution for the Propagation of the Faith" was formed at Lyons, with a view to the promotion of missions by the Romish Church. It now carries on its operations through two councils, one at Lyons, the other in Paris; and it has drawn to itself the support not only of the rest of France, but of the various countries of Europe, and other parts of the world, where Roman Catholics are found. Through its influence and exertions the ancient spirit of missions has been revived in the Romish Church; many of the old missions have been restored to somewhat of their former vigour, and many new ones have been undertaken in various parts of the world, including our own and other Protestant countries—to which, indeed, their eyes appear to be specially directed. To show the extent of their missions in the present day, we shall here state the number of bishops and priests engaged in them, and the amount of money expended on them.

In 1844 the number of bishops and priests engaged in them was as follows:—

	Bishops.	Priests.
In Europe.....	27	843
„ Asia.....	71	2736
„ Africa.....	6	168
„ America.....	28	890
„ Oceanica.....	7	113
.....	139	4750

Since that time the number of labourers of one description

Missions.

Missions. or another, including Sisters of Charity, appears to have been greatly increased. (*Annals*, vol. v., pp. 138, 148, 153.)

In 1856 the receipts of the Institution for the Propagation of the Faith amounted to 3,905,067f. 71c., which, taking the exchange of the franc at 10d., makes L.162,711, 3s. 1d. sterling; and its expenditure on account of the missions was 3,689,663f. 22c., or L.153,735, 19s. 4d., viz:—

Missions in Europe.....	819,221f.	70c.
„ Asia.....	1,314,796	87
„ Africa.....	277,642	0
„ America.....	909,397	35
„ Oceanica.....	368,605	30
	3,689,663	22

The following were the receipts and expenditure in Great Britain, her colonies in America, the United States, and in India and China, in 1856:—

	Receipts.		Expenditure.	
England.....	40,825f.	65c.	123,500f.	0c.
Scotland.....	3,528	0	58,000	0

Chinese Empire.....	—	—	347,031	71

295,083f. 74c. 1,840,533f. 63c.

It thus appears that the expenditure on the missions in Great Britain and the other countries now named, forms just about one-half of the whole expenditure of the Society on missions throughout the world. (*Annals of the Propagation of the Faith*, vol. xviii., pp. 150, 158, 160, 162, 174, 179, 181, 183.)

As regards the methods of conversion employed by Protestant and Romish missionaries, there is little in common. There is one means of regeneration employed by the latter which seems quite a favourite measure with them, and is deserving of notice as a specimen of their system,—the baptizing of sickly and dying infants, a singular compound of gross error, frivolity, and deception.

“For a long time”—(we here quote the *Annals of the Propagation of the Faith*)—“it was not possible to regenerate in the waters of baptism the children of infidels—only in some isolated places. The number of those who went from the cradle to the grave with the seal of baptism was still small, and for this reason we have seldom made mention of it in our *Annals*. But of latter years this benefit has been extended in a most consolatory degree. Our missionaries, with the assistance of the alms of the Association, have succeeded in rendering it general among the principal Christian congregations of Asia. We shall soon have much to do to reckon the young elect with which they will people heaven. Even now the account of those whom they have sent there is sufficiently large to draw forth the gratitude and the admiration of our faith; and accordingly we offer it to our associates with a religious eagerness. It will consist of figures only; but figures are very affecting when they express a multitude of souls gained for the happiness of heaven.”

“The mission of Su-tchuen,” writes his lordship, Doctor Perocheau, vicar-apostolic of Su-tchuen, “continues its work of baptizing children in danger of death, and the Lord continues to bless it. Each year the number of those whom they regenerate goes on increasing:—

It was in 1839.....	12,483
„ 1840.....	15,766
„ 1841.....	17,825
„ 1842.....	20,068
„ 1843.....	22,292
This year (1844) amounts to.....	24,381

Missions. “We have remarked that about two-thirds of the number of these children died in the year in which they were baptized. Thus, out of the number of 1844, 16,763 winged their flight a short time afterwards to everlasting bliss.

“We pay some Christian men and women, who are acquainted with the complaints of infants, to go, seek out, and baptize those whom they find to be in danger. It is easy for them to meet them, particularly in the towns and large villages, where on fair days there is to be seen a crowd of poor people, reduced to the greatest poverty, who come to seek alms. It is in winter especially that the number is highest, because want is more pinching at that time. You see them on the roads, at the gates of the towns and villages, or crowded together in the streets; poor people without number, with hardly any clothing, having neither fire nor lodging, sleeping in the open air, and so attenuated by the protracted torture of hunger, that they are nothing but skin and bone. The women, who are in this case the most to be pitied, carry on their backs children reduced to the same extremity as themselves. Our baptizing men and women accost them in the gentle accents of compassion, offer them gratis pills for their little expiring creatures, give often to the parents a few farthings, always with great kindness of manner, and an expression of the liveliest interest in their situation. For these poor creatures it is a sight of transport almost unheard of. They willingly allow our people to examine into the state of the child, and spill on its forehead some drops of water, which they declare to be good for it, while at the same time they pronounce the sacramental words.” (*Annals of the Propagation of the Faith*, vol. vi., pp. 322, 324.)

Dr Perocheau does not appear to reckon so much on the success of his mission among the adult population as with these poor children, and he glories in the great increase of their numbers. In a letter dated Sept. 4, 1848, he thus writes:—“In spite of the obstacles which the mandarins throw in the way of the conversion of the infidels, we have received as catechumens 1280 neophytes, and baptized 888 adults in the year. God be praised! But our Angelical Society it is which gives us the greatest consolation. The number of the children of the infidels baptized in danger of death continues constantly to increase. This year it amounts to 84,416, about two-thirds of whom, already in possession of unutterable felicity, will love and praise God eternally. The more we receive aid from Europe, the more will this work extend its benefits. We have opened in several cities small shops, where Christian physicians gratuitously distribute pills for young persons who are sick, and generously give attention of all kinds to the children brought to them. This work produces marvellous effects, causes a very large number of children to be baptized, and singularly pleases the heathens. In order to explain the prodigious success of our angelical work, you must be informed that all China is covered with poor persons, reduced to the last degree of wretchedness, and burdened with numerous families. Their children lack everything; no food, no clothes, almost no shelter. The mothers die of hunger and cold; the infants they support perish with them. It is these nurses which give an abundant harvest to our baptizers, who seek these poor wretches in preference to others, accost them with kind words, testify a warm interest in their young families, give pills, and sometimes add alms. They are therefore regarded as angels descended from heaven, and are easily allowed to baptize the perishing little ones. Some of our physicians have often effected wonderful cures, and though their skill is small, enjoy extraordinary repute. Hippo-

¹ We have included in this sum 58,000f. on account of “Missions of the Rev. Father Oblates of Mary in England and Ireland,” not being able to apportion the particular sums appropriated to each country.

Missions. crates was not lauded so much. Sponges are here unknown. We fell on the idea of getting some from Macao, as more convenient than cotton for baptizing. The pagans admire these sponges, and regard them as an infallible remedy. They are delighted at seeing the foreheads of their sick children laved with so marvellous an instrument. We hope that next year the number of our baptized infants will reach a hundred thousand; by and by it may amount to two hundred thousand a year if you send us good support. In no other part of the world can your money achieve the salvation of so many souls. After the conversion of China, which contains more than three hundred million of inhabitants, you may compute the multitude of little Chinese which will every year ascend to heaven."

Dr Retord, bishop and vicar-apostolic, Tong-King, after reporting the baptism of 9649 infants in 1849, states as among the means of this success the following:—"A collection is made, and a small capital acquired. This capital is employed in trade, or laid out in the purchase of a piece of land. With the income we purchase boards to make coffins and religious and funeral tokens; then, when the children of the pagans die, the society give them a solemn interment, with music and a drum, and a troop of little children of both sexes, who follow the procession. The heathens are ravished with the pomp; so that when one of their children falls sick, they of their own accord entreat us to go and baptize it. There is in the mission at present a great zeal for this work; but to sustain this ardour I must get many books, images, and chaplets made. All the objects of the kind you have sent me are used for this purpose; but they are not enough. I am getting made here many chaplets for this purpose. Nevertheless, we shall never reach the number of baptisms in China, for the people here are very fond of their children." (*Annales de la Propagation de la Foi*, 1850, p. 127, and 1851, p. 273, in *Journal of Sacred Literature*, April 1852, p. 23.)

M. Fontaine, missionary-apostolic in Cochinchina, gives the following account of the plans followed in that country:—"You will receive with pleasure some particulars concerning one of our works, little in appearance, but productive of great results for the salvation of souls; I allude to the pagan children baptized on the point of death. Every one can take part in it; but we may say that it is principally the business of the women: they can more easily get into the houses, and people are less on their guard against them than against men. Through their charitable cares a considerable number of these little creatures have hardly received life before they exchange it for the unending joys of paradise.

"In a village of which the mayor is a Christian there exists a house of nuns, whom his lordship (the bishop) sends out in different directions to look for these hapless children. They go generally two by two,—an old one and a young one; and while the elder one enters into conversation, the other, who, in good manners, should leave her to speak, draws near the mother, who is holding the sick child, or sits down near the mat on which it is left. She fondles it, takes it in her arms, and whilst she caresses it, she succeeds in dropping on its forehead a little water out of a bottle which she keeps concealed in her long, wide sleeve. (*Annals of the Propagation of the Faith*, vol. vi., p. 328.)

The missions in the South Sea Islands have been established but of late years; but here also we find a similar practice. "I have always with me," says Dr Bataillon, bishop and vicar-apostolic, "a flask of scented water and a flask of plain water. I begin with sprinkling a little of the scent on the head of the infant, under pretence of comforting the babe, and whilst the mother takes pleasure in spreading it over the baby's face, I dexterously change the flask, and use the water which conveys regeneration, without any suspicion being excited of the nature of the action."

We also read the following statement in a letter inserted in the *Annals*:—"The child which we baptized so hastily, since it seemed at its last hour, died last night, to our great joy, for its death ensures its eternal happiness."

We leave these statements to speak for themselves. We would scarcely have ventured to give them if they had not rested on the most undoubted Roman Catholic authority.

(For a general history of Protestant Missions, we may refer to Dr Brown's *History of the Propagation of Christianity among the Heathen*, in 3 vols., third edition, 1854. We regret we are not able to name any general history of Roman Catholic missions.) (W. B.—N.)

MISSISSIPPI, one of the largest of the southern states of the North American Union, is bounded,—N. by Tennessee, W. by the Mississippi River, which separates it from Arkansas and Louisiana, S.W. by the Pearl River, S. by Louisiana and the Mexican Gulf, and E. by Alabama. It lies between N. Lat. 30. 10. and 35., and W. Long. 88. 12. and 91. 36. It extends for about 330 miles from N. to S., with a mean breadth of 120 miles, and contains an area of 47,156 square miles, or 156 square miles more than that of New York. The state, in its physical aspect, presents no prominent hill-ranges, but abounds in rivers. The Mississippi with its tributaries on the west, the Tombigbee and Pascagoula on the east, Pearl River in the central section, and the Tennessee skirting the north-east corner, drain the entire territory. Among the tributaries of the Mississippi the principal are,—the Yazoo, which flows from N.E. to S.W., almost parallel with the main stream, and joins it near Vicksburg; and the Big Black, a smaller tributary, which joins the Mississippi some forty miles lower down. All of these rivers are navigable for steamers. A chain of lagoons and bays form the southern or gulf coast of Mississippi, among which are Pascagoula Inlet, Biloxi Bay, St Louis Bay, &c. The upper portion of the state, which has been in cultivation for about twenty years, possesses an undulating surface heavily wooded with oak, hickory, &c.; it is, however, but scantily watered. The uplands produce abundantly, but only for a short time; while the soil of the valley lands is much firmer, though liable to be submerged by quantities of sand brought down from the higher grounds during the heavy floods. The prairie or Tombigbee country covers the north-eastern section of the state. Its surface is uniformly level, presenting an almost unbroken flat, with scarcely a tree, covered with rank grass, and dotted with pools and marshes. The soil, formed of a dark heavy loam, has, however, surprising strength and fertility. East Mississippi, along with the southern and south-eastern sections, is the healthiest part of the state: the air is pure and the water good. Its soil varies very much in quality, in some quarters being deep and rich, while in others exceedingly poor. It is generally well adapted for pasturage; and indeed the rearing of cattle forms the chief employment of the inhabitants. The section of the state washed by the Gulf of Mexico is well known for its healthy watering-places, which are frequented during the hot season by the wealthier classes of the entire southern country. The interior of this portion of the territory between Pascagoula and Pearl Rivers is occupied by a sandy, broken tract, covered with pines, which have been recently used for the production of turpentine. The most fertile soil of the whole state, however, is to be found in the valley of the Mississippi, where it possesses all the strength without the adhesive and corrosive nature of the prairie land. The climate of this region is likewise not insalubrious. A great drawback, however, exists here in the frequent occurrence of inundations, which have as yet not been wholly prevented by the construction of dykes sufficiently strong and elevated.

In such portions of the state as are removed from stagnant waters, which in this climate must always be deleteri-

Mississippi.

ous to health, and where access to pure spring water is to be had there is perhaps no part of the Union where the inhabitants enjoy better health. Though bilious attacks are generally prevalent, the people are exempt from pulmonary and catarrhal affections, so fatal in the more northern states. The central and southern sections have a climate similar to that of South Alabama, Georgia, and the northern portions of Louisiana and Florida.

Agriculture.

Every product of the South may be grown in Mississippi, including the sugar-cane,—which, however, is but little cultivated,—tobacco, corn, rice, cotton, potatoes, indigo, grapes, oranges, figs, peaches, &c. Cotton, the grand staple of the state, comes to perfection in every part of it, and is almost the exclusive object of attention with agriculturists. In 1850 there were 15,110 cotton plantations, producing annually more than five bales each, being a larger number than in any other state except Alabama. The cotton crop of Mississippi is one-fifth of the whole North American growth, and is almost exclusively the product of slave labour. The number of slave-holders at the last census was 23,116; and of these 3640 possessed only one slave, 6228 held from one to five slaves, 5143 from five to ten, 4015 from ten to twenty, 2964 from twenty to fifty, 910 from fifty to a hundred, and 216 from one hundred to five hundred. In 1850 the state contained 33,960 farms, comprising 3,444,358 acres of improved land, whose cash value amounted to L.11,403,631; that of the implements employed thereon to L.1,190,609. The number of horses, asses, and mules, at the same date, was 170,007; of neat cattle, 733,970; sheep, 304,929; and swine, 1,582,734. There were also 137,990 bushels of wheat produced, 22,446,552 bushels of Indian corn, 5,003,277 of Irish and sweet potatoes, 193,401,577 lb. of cotton, 2,719,889 lb. of rice (rough), 49,960 lb. of tobacco, and 559,619 lb. of wool. The above are the leading agricultural products. Besides these there are rye, oats, barley, buckwheat, hay, hops, seeds, butter and cheese, pease and beans, fruit, honey, wax, poultry, wood, molasses, sugar, silk, wine, &c.

Manufactures.

Manufactures are in their infancy in Mississippi, and do not seem likely to make any early advances. The capital invested at last account was but L.361,962; the production about L.625,000; and the hands employed, 3178. Of this capital L.7916 was employed upon cotton manufactures, and L.20,883 upon iron castings.

Commerce.

Commerce is confined almost entirely to the operations connected with cotton, and to the retail trade; and although there are several towns of considerable population, nearly the whole foreign commerce of Mississippi is conducted through the cities of New Orleans and Mobile.

Internal communication.

Within the last two years much spirit for internal improvements has been evinced in Mississippi. The Southern Railroad extends from Vicksburg to Brandon, 60 miles, and it is intended to connect it with the railway system of Alabama. The New Orleans, Jackson, and Great Northern Railroad will traverse the entire state in the direction of Nashville; and some portion of the work is already completed. The Central Railroad is also being constructed with vigour, and is intended to connect the capital with Holly Springs, and, pursuing a northerly direction, with the mouth of the Ohio River. The Charleston and Memphis Railroad passes through a small part of the northern portion of Mississippi. From the facilities of construction, it may be asserted that the railway system of Mississippi will soon exceed that of any other south-western state. In 1855, 239 miles of railroad were completed, and 755 were in progress.

Constitution.

The state constitution of Mississippi was adopted in 1817, and revised in 1832. Suffrage is free. The legislature consists of a Senate and House of Representatives, and meets biennially. The governor is elected for two years, and receives a salary of L.800 per annum. The

judiciary consists of a high court of errors and appeal, circuit courts, a superior court of chancery, district courts of chancery, and a probate court in each county. All the judges are elected by the people, this being one of the earliest states to adopt that system, the bitter fruits of which are beginning to show themselves in many quarters.

Mississippi.

In 1855 the expenditure of the state government was L.65,260, the principal items of which were—Executive department, L.2900; judiciary, L.21,500; university, L.3280; internal improvements, L.20,600. The net revenue amounted to L.100,775, the sources of which were,—Taxes, L.68,970; internal improvement fund, L.13,200; school land fund, L.12,400. In 1856 there were 15,913,532 acres of land subject to tax.

On the 1st of January 1856 the Northern Bank of Mississippi had a capital of L.50,000; loans and discounts of L.101,750; specie, L.1619; circulation, L.67,516; deposits, L.7000.

An asylum for the blind, one for the deaf-and-dumb, and Education, a lunatic asylum, are in operation, under the support of the state, at Jackson, where the penitentiary is also located. There is no uniform common school system for the whole of the counties; each county has its school lands, allotted by government and leased for long periods, the money being invested for the benefit of the schools. There is also a fund made up in the several counties; but the whole is very inadequate to the wants of the state. In 1850 there were 11 collegiate institutions in the state, with 862 students; 782 public schools, with 18,746 pupils, and L.53,000 income; and 171 academies or other schools, with 6628 students; total number attending school, 48,803. There were at the same time 1016 churches, of which 385 were Baptist, 454 Methodist, 13 Episcopalian, 143 Presbyterian. Four tri-weekly papers were published, 46 weekly, and several daily. The public libraries of schools, colleges, &c., contained 22,000 volumes.

The settlement of Fort Rosalie near Natchez was the first permanent one made in Mississippi by the French, under Bienville; but a general massacre of the whites soon followed, which left the country again in the hands of the savages. A series of conflicts ensued, terminating generally in favour of the whites; and at the peace of Paris 1763 Mississippi became a part of the English territory. Settlers from Nova Scotia and the eastern states soon followed fast upon each other. The district was surrendered to the United States after the peace of 1783; and in 1804 the Mississippi territory comprised the whole of the present state of Alabama, from the 31st to the 35th degree of north latitude. This territory was organized under that name in 1798; but in 1818 the eastern portion was separated, and the remainder was admitted into the Union as the state of Mississippi.

The following statistics will show the progress of Mississippi in population from the earliest records:—

	1800.	1810.	1820.	1830.	1840.	1850.
Whites.....	5179	23,024	42,176	70,443	179,074	295,718
Free coloured	182	240	458	519	1,366	930
Slaves.....	3489	17,088	32,814	65,659	195,211	309,878
Total.....	8850	40,352	75,448	136,621	375,651	606,526

The following are the principal towns of Mississippi, with their population at the last census:—Vicksburg, 3678; Natchez, 4334; Columbus, 2611; Jackson, 1872; Yazoo City, 1910.

MISSISSIPPI (*Missi Sipi*, "The Great Water"), the most important river in North America, and, with the Missouri, its principal affluent, or more properly its main branch, the longest river in the world. In N. Lat. 47. 10., W. Long. 94. 54., and at a height of 1680 feet, on the summit of the Hauteurs

Mississippi.

de Terre, a dividing ridge from the Red River basin of the north, are the sources of this great river. At first, a little rivulet, it pursues its timid course over sand and pebble, ever and anon blending with kindred streams, and at length forming a small lake. Another rivulet issues thence with increased velocity, giving rise to more decided bends, and emptying at last into the Itasca Lake. There, beyond the haunts of civilized man, the "father of waters" takes his course through glades, over crags and precipices,—now a broad stream, and now a confined impetuous torrent,—gradually gaining in strength and vigour as kindred waters meet and sweep on together, leaving the savage intractable forest, and the creatures which inhabit it, to be cheered by sounds of industry and toil as it nears the ocean.

After flowing in a very tortuous course through various climates and eighteen degrees of latitude, and washing the shores of many populous states, the Mississippi empties itself through several mouths into the Gulf of Mexico, in Lat. 29. N., Long. 89. W.

The following table is made up on the authority of the engineer Nicollet, who in the service of the American government explored this region:—

Distances on the Mississippi.

	From Gulf of Mexico.	Altitude.
	Miles.	Feet.
New Orleans cathedral	104	10'5
Mouth of Red River.....	340	76
Natchez	406	86
Mouth of Yazoo	534	...
New Madrid, Missouri.....	1115	...
Mouth of the Ohio, north side	1216	324
St Louis cathedral	1390	382
Mouth of Illinois River	1426	...
Prairie du Chien	1932	642
Upper Iowa River	1978	...
Mouth of St Peter's River	2192	744
Falls of St Anthony	2200	856
Lake Cass.....	2775	1402
Itasca Lake	2890	1575
Utmost sources of the Mississippi.....	2986 ¹	1680

If the Missouri be considered as a continuation of the Mississippi, the length of the entire river will be 4350 miles.

The following table, prepared for his *Geographical Dictionary* by Mr Darby, gives the area of the Mississippi valley, or the region drained by that river and its tributaries:—

	Miles.
Valley of the Ohio.....	200,000
Mississippi proper	180,000
Missouri	500,000
Lower Mississippi	330,000
	1,210,000

The valley of the Mississippi comprises nearly one-half of the territory of the American states.

Professor Riddell of Louisiana estimates the true superficial area of the delta of the Mississippi, or that portion of its basin below Baton Rouge, where the last bluffs show themselves, at 15,000 square miles,—the alluvial mass being 200 miles in length, 75 miles in width, and $\frac{1}{4}$ th of a mile in depth. The rise of the basin of the river is only 9 feet before reaching New Orleans, and beyond that not more than an average of 6 inches in the mile. The delta gains upon the sea not more than a mile in 100 years; and Professor Lyell estimates that 100,000 years were required in its formation.

Large sums are continually appropriated by the government for deepening the channels, but hitherto without permanent effect. In the early part of 1857 a fleet of

vessels were aground in these passes at the same time. Old channels are continually being filled up, and new ones formed.

As indicative of the vast growth of the Mississippi valley, it may be stated, that in 1790 the whole population of the valley amounted to 205,280; in 1800 to 582,619; in 1810, 1,337,946; in 1820, 2,419,369; in 1830, 3,794,477; in 1840, 5,983,707; in 1850, 8,641,754; and in 1857, may be safely set down at between 10 and 11 millions. Even this is but a density of about 7 persons to the square mile, while the average density of the Atlantic states is 19·98 to the square mile, and of the middle states 57·79: that of England is 332 to the square mile. With this last density, the valley of the Mississippi could accommodate more than 400,000,000 persons, or about one-half of the present population of the earth.

The inauguration of steam on the western waters in 1811 was the first step in the enormous progress of this valley, and without which it must have remained a wilderness, notwithstanding the great lines of communication that have been opened to the Atlantic coast. In 1815, 14 steamers were employed; in 1829, 230; in 1843, 600; and in 1856, 1500. The total commerce afloat in 1852 was estimated by the secretary of the Treasury, Mr Corwin, at L.70,729,738, or, with the great lakes, L.136,245,042, nearly equal to double the foreign imports and exports together of the entire Union at that time.

Steamers of magnificent size and accommodation ply on this river, and make the trip from New Orleans to St Louis in five days, to Louisville in about the same time, to Cincinnati in six or seven days, and to Pittsburgh (2175 miles) in ten days, at a charge for passengers of the first class ranging from L.3 to L.5. In no part of the world can such economy in travelling be found.

Below the mouth of the Ohio the depth of the Mississippi varies from 90 to 120 feet, and its breadth from 600 to 1200 yards. At New Orleans the width is $\frac{3}{4}$ d of a mile, and the depth 100 feet. The lower river is restrained within its channel by embankments thrown up with great labour and expense. The average height of the flood of the river below the Missouri is 15 feet; at the mouth of that river, 25 feet. Below the Ohio the rise is often 50 feet; at Natchez it seldom exceeds 30 feet; and at New Orleans 12 feet. Large ships have seldom ascended the river higher than Natchez.

The Mississippi had been casually visited in 1542 by De Soto, but not in any proper sense discovered. He saw but a few leagues of its course, from which no idea was obtained of its rise, direction, extent, or relations with the continent. It is mentioned in Coxe's *Carolana*, that in 1678 a number of persons went from New England to Mexico, in which expedition they crossed the Mississippi, and on their return gave an account of their discovery to the governor at Boston. During the missionary labours of the Jesuits in Canada, two fathers, Joliet and Marquette, having heard vague rumours of the existence of the "Great River" left Mackinac in 1673, ascended the Fox River from Green Bay in canoes, passed to the Wisconsin, and down that river to the vast waters of the Mississippi, which they navigated for 1100 miles. Some years afterwards La Salle reached the Mississippi from Canada, and, returning to France, fitted out an expedition to explore the river from the gulf. The expedition made land on the 1st January 1685, 100 miles westward of the mouth of the river, which but a small portion of the party succeeded in reaching, and returned thence to Canada. In 1700 M. Iberville colonized the country; in 1769 it was ceded to Spain; in 1800 was retroceded to France; and in 1803 passed into the possession of the United States. (J. D. B. De B.)

¹ Schoolcraft makes the distance 3160 miles.

Mississippi.

Missouri.

MISSOURI, one of the middle western states of the North American Union, bounded on the N. by Iowa, E. by Illinois, S.E. by Kentucky and Tennessee, S. by Arkansas, and W. by the Indian territory and the territories of Kansas and Nebraska. It is the largest of the states in the American Union, with the exception of Texas and California, having an area of 67,370 square miles.

Physical aspect.

A large portion of the south-eastern section of the state, to a considerable distance W. from the Mississippi River, is low, swampy, abounding in lakes, and subject to inundations. Beyond this the country swells into roundish hills, rising continuously to the mountainous districts of the lead mines. Farther still it is broken and hilly, until it reaches the boundless prairies of the western limits of the state. The lands of Missouri are generally more loamy and friable, and the soil less stiff, than upon the Ohio. The rich uplands are of a darkish gray colour, except about the lead mines. The poorer uplands are generally covered with white oak, and are of a light yellow colour; the prairies are for the most part level, and of an intermediate character between the richer and poorer uplands. Those which are alluvial, as in the N. between the Mississippi and Missouri, are always rich; as are also the bottoms of all the water-courses. Those of the Missouri are loamy, intermixed with sand; those of the Mississippi are blacker, more clayey, less sandy, and, if not so immediately fertile, are more inexhaustible. Great varieties of soil abound in Missouri, from best to worst, and there are extensive tracts of each; but in general the better districts are of great fertility, indicated by a rank and abundant vegetation.

The Ozark Mountains traverse a large part of Missouri. The Missouri River, which gives name to the state, and the Mississippi washing its boundary, give to Missouri the navigation of two of the greatest rivers in the world. By means of this navigation she can open her commerce with the Gulf of Mexico, and by the waters of the Ohio with the Atlantic states. The tributaries of the Missouri within the state are the Chariton and Grand Rivers from the N., and the Osage and Gasconade from the S.; whilst the Mississippi receives the Salt and the Maramec. The St Francis and White Rivers are on the south-eastern part of the state, and pass on to Arkansas.

Mineral resources.

The mineral wealth of Missouri has long been proverbial. Of lead the state produces immense quantities. The iron mountains are estimated to contain 600,000,000 tons of that metal. Copper is next in importance, and has been discovered in the Current River and on the Maramec, and in the southern parts of the state. Cobalt occurs in the form of black oxide and sulphuret, and is found in thin layers or in connection with manganese. Zinc also abounds in the lead mines, and might be worked to great advantage. It is estimated that the average quantity of silver contained in the Missouri lead mines is from six to eight ounces to the ton; but it has never been attempted to separate this before bringing the lead to market. Tin also is found. Nickel accompanies the copper; and cobalt and manganese are abundant over the southern parts of the state. Limestone is found in great quantities, and also marbles, beautifully crystalline and veined; gypsum, sandstone, porphyries, sienite, saltpetre, kaolin, and inferior clays. Bituminous coal exists in vast beds on both banks of the Missouri; and the largest body of cannel coal known is in Callaway county. A geological survey of the state has been ordered, and is in progress. The coal trade of St Louis alone in 1856 was estimated, on high authority, at L.528,150. The coal beds of the state, says the state geologist, can furnish 100,000,000 tons annually for 1300 years. In 1855 nine iron establishments at St Louis produced L.521,000, and the whole capital of the city invested in that branch of industry was about L.625,000. The smelting works engaged in Missouri in 1856 were estimated to produce 35,000 tons of pig-

metal; and the state geologist says,—“There is ore enough of the best quality above the surface of the valleys to produce 1,000,000 tons per annum for 200 years, which would be worth L.1,042,000,000. But this is but a small part of the iron resources of the state, which would reach nearer L.20,000,000,000.” (*Western St Louis Journal*, vol. xv., No. 3.)

Missouri.

Below the mouth of the Ohio the climate approximates to that of the southern states. Throughout the state, however, it is generally of a variable character. The transitions are in many parts rapid and unfavourable to health. Winter commences about the last of December, when the Missouri becomes one solid mass of ice; and is mostly over in February. The snows are not deep. The greater part of the summer is intensely hot, though the freedom of the country from mountains admits of more or less breeze. The air is dry and pure. Autumn is serene, temperate, and delightful. Except in deep bottoms and unfavourable situations, however, the chances of life are as great in Missouri as in most countries reputed to be healthy.

Agriculture.

Farming is very easy. The soil is readily worked, and generally fitted for the plough. Fencing material is the only deficiency, and artificial hedges have been resorted to. In 1850 there were 54,458 farms or plantations, containing 2,938,425 acres of improved and 6,794,245 acres unimproved lands. The average number of acres to each farm was 179, and the average value, L.242: total value of farming lands, L.13,172,000; value of farming materials, L.829,500. The chief agricultural productions of the state were,—Swine, 1,702,625; wheat, 2,981,652 bushels; oats, 5,278,079 bushels; Indian corn, 36,214,537 bushels; potatoes, 1,274,511 bushels; hemp, 16,000 tons; cotton, 121,122 lb.; tobacco, 17,113,784 lb.; wool, 1,627,124 lb. It will thus be perceived that tobacco, hemp, Indian corn, and wheat are the leading agricultural products of Missouri. Among the smaller products were,—rye, barley, buckwheat, hay, hops, seeds, wax, honey, wood, flax, maple, sugar, molasses, rice, silk, wines; besides dairy, garden, and orchard products. In the state there were 5762 families holding 1 slave; 6878 holding more than 1 and under 5; 4370 holding 5 and under 10; 1810 holding 10 and under 20; 345 holding 20 and under 50; 420 holding over 50. The value of the real estate of Missouri in 1850 was L.13,917,128; personal, L.6,623,600 as rated for taxation; but the true value of both was given at L.28,593,270.

This state, like others of the west and south-west, has as yet made but small advances in the manufactures. The latest official reports show that the capital invested was L.1,891,600; raw material used, L.2,593,000; hands employed, 16,870; wages paid, L.663,500; annual product, L.4,947,760. Of the above capital L.21,250 was invested in cotton manufactures, L.4375 in woollen, L.129,000 in pig-iron, L.39,000 in castings, L.8770 in wrought iron, L.62,500 in breweries and distilleries. The present amount of manufacturing capital in Missouri may be stated at double of the above statistics. In 1855, 603,352 barrels flour were manufactured in St Louis alone.

Commerce.

The large and growing commercial importance of St Louis, the chief city of Missouri, is universally acknowledged. Its chief receipts in the year ending 1st January 1856 were,—1,307,818 sacks corn; 331,368 bushels flour; 315,556 pigs lead; 18,000 hhds. and packages tobacco; 407,000 sacks salt; 58,215 hhds. sugar; 81,328 barrels and 8712 casks pork; 52,046 barrels molasses; 22,767 casks and 959,635 pieces bacon; 98,000 barrels and kegs lard; 93,186 bales hemp; 136,610 sacks coffee; 21,000 barrels and tierces beef; 64,868 sacks barley; 1,769,768 sacks wheat; 68,488 barrels whiskey. The number of arrivals of steamboats in the same year was 3449, of a tonnage of 918,791. Real estate, which in 1820 reached in value but L.857, in 1853 was valued at L.8,600,000. The foreign direct trade of

Missouri.

Internal
improvement
cents.

Missouri is very small, and scarcely exceeds L.200,000 or L.250,000.

The internal improvement system of Missouri is so devised that the business to be conducted will receive accessions from almost every road that can be constructed to the W. of the Mississippi. Diverging from a common point, and extending to the state line, her railroads will each form the basis of a system in the adjoining states; and as the revenues of the great west and of the Mississippi are developed, their business must increase to an amount almost incredible. The state is very liberal in its grants of aid to the railroads. Among those in progress are,—the Pacific Railroad, extending westward to Kansas, &c.; the Hannibal and St Joseph; the St Louis Iron Mountain; the North Missouri, connecting with Iowa: estimated length of these roads, 922 miles; and estimated cost, L.8,600,000. The actual miles in operation in the state are from 75 to 100. Missouri has pledged her state credit to the extent of L.3,960,000 in aid of this magnificent system of public works.

The state constitution of Missouri was adopted in 1820, but was amended in 1822, 1843, 1848, and 1850. The right of suffrage is free to all citizens of the United States who have resided one year in the state. The legislature meets biennially. The governor is elected for four years. The judiciary consists of a supreme court, circuit, county, and justices' courts, &c. The judges are elected by the people.

In 1856 the total expenditure of the state government was L.98,810, of which the poll tax was L.8224; land tax, L.32,660; slaves, L.13,240. The state debt of Missouri, as the railroads progress, will soon reach L.1,300,000. The banking capital in 1856 was L.251,000, with a specie basis of L.380,000, and a circulation of L.579,850.

There is a state lunatic asylum, with 80 inmates; a deaf-and-dumb asylum, with liberal endowment; an asylum for the blind; and a state penitentiary.

The school fund reaches in amount L.139,500, the revenue from which, and from state and from public schools, reaches yearly L.29,000, which is distributed among the counties. In 1850 there were 9 colleges, with 1009 students; 1570 public schools, with 51,754 students; and 204 other schools, with 8829 pupils. There are 2 medical schools, with 210 students; and the state university is liberally endowed. There were 878 churches, of which 300 were Baptist, 250 Methodist, 125 Presbyterian, 65 Catholic; value of church property, L.322,732. About 10 daily and 75 weekly or monthly newspapers are published in the state. The population of St Louis, the chief town, in 1850 was 77,860, and in 1857 was estimated at 125,000. The following statistics will show the progress of Missouri in population from the earliest records:—

Population.	1810.	1820.	1830.	1840.	1850.
Whites.....	17,227	55,988	114,795	323,888	592,004
Free coloured.....	607	347	569	1,574	2,618
Slaves.....	3,011	10,222	25,091	58,240	87,422
Total.....	20,845	66,557	140,455	383,702	682,044

By the state census of 1852, the white population was 623,319; free coloured, 2526; slaves, 87,172;—total, 713,017.

The region now known as Missouri was included by the French and Spaniards in the Illinois country, but was popularly and historically known as Upper Louisiana. In 1755 St Genevieve, the oldest town in the state, was founded, and in 1764 St Louis. Early settlements were made from Canada. When this country came into the possession of the United States in 1803, it was divided into two territorial governments,—Orleans, including the present Louisiana; and Louisiana territory, embracing Missouri and the

VOL. XV.

upper regions of the Mississippi. In 1812 the name was changed to Missouri Territory; numerous American pioneers flocked in from Kentucky, Tennessee, Ohio, &c.; and American habits, institutions, and laws, soon became predominant. In 1817 application was made for admission as a state into the Federal Union, which led to fierce and stormy debates in Congress regarding the admission or exclusion of slavery. The discussion raged for two years, threatening the existence of the Union, and was only adjusted by a compromise, in which it was agreed that the institution of slavery should be recognised in Missouri, but in no other state north of the latitude of 36° 30' which might be formed out of the territories of the Union. This compromise was abrogated by a new one made upon the admission of California; and when the territorial governments of Kansas and Nebraska were formed, the abrogation was distinctly referred to and confirmed. The supreme court of the United States has recently pronounced such a compromise to be *unconstitutional*, thus leaving the territories open to slavery or not, as may be determined upon by their inhabitants.

MISSOURI River. The Missouri River has its sources high in the Rocky Mountains, in Lat. 45. N., and Long. 110. 30. W., almost in the regions of British America. Its course is at first nearly N. to the Great Falls, when it bends to the E.N.E. till it joins the White Earth River, whence its course to its confluence with the Mississippi is generally S.E. But little serious impediment to navigation is interposed lower down than the Great Falls, a distance of 2575 miles from the mouth. The Missouri drains a basin of half a million square miles, and its whole length to its junction with the Mississippi is estimated at 3090 miles. Its course throughout is irregular and turbulent, abounding in rapids and bars. The United States engineers, who surveyed its whole extent in 1853–54, arrived at the conclusion that a steamer loaded, and drawing 24 inches, could navigate, from the opening of the season until the 1st of September, as far as Fort Union; and that one drawing 20 inches could go up even beyond Fort Benton. From the very elaborate report of these engineers, employed by the government to survey the several routes for a railroad to the Pacific, we condense the following interesting particulars in regard to the course of the river, its length, characteristics, and tributaries.

The Missouri enters the Mississippi in Lat. 38. 50. 50. N., and Long. 90. 13. 45. W. of Greenwich. Below the mouth of the Kansas its course is nearly E., and lies almost entirely in the state of Missouri. This portion is continuously settled with flourishing cities and towns; and the soil is of surpassing fertility, abounding in coal, iron, and other minerals. Its average velocity in this section is a little over five miles an hour. Concealed snags and sawyers are liable to occur in any part of the river, and its banks are heavily wooded from the mouth of the Kansas to the Mississippi. The principal tributaries between the mouth and Fort Leavenworth are the Osage, Grand, and Kansas Rivers, which are navigable,—the first, for six months in the year, 200 miles; the second at all seasons; and the last 150 or 200 miles, obstructed, however, by two sets of rapids. The valley of the Missouri possesses great resources for future wealth and influence. From the mouth of the Kansas to near the parallel 40. 38. N. Lat., this river separates the state of Missouri from the Indian territory, and from that point to the Big Sioux, separates Iowa from the Indian territory. Before reaching the Platte, the Nodawa, Little Tarkio, Big Nemaha, Nishnabotana, and Little Nemaha, minor streams, enter the Missouri. In uniting with the Missouri the Platte forms a delta, and debouches through three channels varying from 30 yards to 350 yards in width. The delta is composed of sand-bars, and intersected by numberless sloughs. From its mouth to Fort Laramie the

2 N

Missouri.

Mitau
||
Mitchell.

Platte is 700 miles long, and is less tortuous than the Missouri. Below the fork the bed of the stream is occupied with vast quantities of drifting sand or quicksand, so that the depth may not be more than 3 feet, and cannot be made available, it is thought, for purposes of navigation. The course of the Missouri from the mouth of the Platte to the Kansas is S.E., and its length 236 miles. Carboniferous limestone and coal measures form the principal geological features of this part of the river. From the mouth of the Platte to Fort Pierre the distance is 638 miles; from Fort Pierre to the Big Sioux the direction of the river is S.E. Council Bluff, situated on the left bank, is the last town now seen on ascending the Missouri, and is the *ordinary* head of steamboat navigation. The soil of the bottoms on this part of the river is very rich. The Big Sioux is 100 yards wide at its mouth, and navigable for steamers to the rapids; it is susceptible of improvement. Within a few years the channel of the Missouri has changed here several miles from north to south. From the mouth of the Platte to Fort Pierre the Missouri varies in width from 400 to 1000 yards, and its valley becomes less fertile. From the mouth of the Big Sioux to that of the White Earth the Missouri separates Minnesota from the Indian territory. From the mouth of the White Earth to Fort Clark the course of the river is S.E., and then is S. to Fort Pierre,—the whole distance being 715 miles. Here the great northern bend of the river is found. The Yellow Stone enters still further up, and is navigable 200 miles to the rapids. The channel of the Missouri becomes now entirely choked by sand-bars. In 1853 a steamer ascended in forty-two days to Fort Union, and returned to St Louis in seventeen days more; and but for the ice, steamers might even ascend to Milk River throughout the year, this being the highest point to which navigation has been carried.

The Missouri is affected by two annual floods, which greatly facilitate navigation by larger steamboats. The first and lesser flood is caused by the melting of snows on the prairies, and generally takes place in May; the second is occasioned by the melting of the mountain snows, and occurs in June. Steamers, heavily laden, and bound for the Yellow Stone, should leave St Louis about the middle of April, in order to have the benefit of the June rise. The river above Council Bluff City is closed by ice from about the middle of November to the 1st of April. (J. D. B. De B.)

MITAU, a town of Russia, capital of the government of Courland, situated in a flat marshy country on the Aa, near its confluence with the Drixe, 27 miles S.W. of Riga. The town, which is built principally of wood, covers a large space, and is well provided with gardens and pleasure-grounds. Its streets are narrow, irregular, and are for the most part unpaved. The principal building of the place is the castle, built by Marshal Biron in 1739 on an island inclosed by the Aa canals, and formerly the residence of the dukes of Courland. There are also a museum, an observatory, two public libraries, a gymnasium, and two creditable picture galleries. The manufactures, consisting of linen, leather, and soap, are of little importance; and its trade is carried on chiefly during the great fair which is held here in midsummer. In 1788, after a devastating fire, a great part of the town was rebuilt; and subsequently it was honoured by the residence of Louis XVIII., then travelling under the title of Count de Lille. Pop. (1852) 13,819, about half of whom were Germans and nearly a sixth Jews.

MITCHELL, THOMAS, a philologist, was the son of a riding-master, and was born in London in 1783. From Christ's Hospital he passed as an exhibitioner to Pembroke College, Cambridge, in 1802. As he did not enter into orders, a fellowship which he subsequently obtained at Sidney Sussex College was taken from him at the end of a limited period, and he was forced to support himself by private tuition and by writing for the press. Several essays

in the *Quarterly Review* on Aristophanes, and a metrical translation of the plays of that poet, were the groundwork of Mitchell's reputation. These were followed by editions of five dramas of Aristophanes and the entire works of Sophocles. Mitchell died at his house near Woodstock in 1845.

MITCHELL, Sir Thomas Livingstone, one of the most successful explorers of Australia, was the son of Mitchell of Craighend in Stirlingshire, and was born there in 1792. From 1808 till the end of the Peninsular War he served in Wellington's army. He was then raised to the rank of major, and employed by government to make surveys of the great battlefields in the Peninsula. At a later period the office of surveyor-general of New South Wales was conferred upon him. In this capacity, between 1831 and 1836, he led three exploring expeditions into the interior of Australia, undergoing great hardships, and exposing himself to imminent peril, yet sedulously collecting all possible information, both on geography and natural history. The results of these journeys were the discovery of the Peel River, the Nammoy, and Australia Felix, and the exploration of the courses of the Darling and the Glenelg. Major Mitchell published an account of his three expeditions, in 2 vols. 8vo, London, 1838. While in England superintending this publication he was knighted by the Queen, and received the title of D.C.L. from the university of Oxford. His last great exploring tour was begun towards the close of 1845, and aimed at discovering a route between Sidney and the Gulf of Carpentaria. The result was published in his *Journal of an Expedition into the Interior of Tropical Australia*, 8vo, London, 1848. Sir Thomas Mitchell died at Sydney in October 1855, and was honoured with a public funeral.

MITCHELSTOWN, a market-town of Ireland, county of Cork, pleasantly situated on the slope of a hill near the Funcheon, 30 miles N.N.E. of Cork. The town consists of a large square and two main streets, and contains several well-built houses. It contains a handsome parish church, a large Roman Catholic chapel in the form of a cross, a national school and library, besides a charitable institution, called Mitchelstown College, endowed for the maintenance of twelve gentlemen and eighteen gentlewomen of the Protestant faith. The inhabitants trade in pigs, grain, and butter; while in the vicinity there are both flax and blanket factories. Near the town is the seat of the Earl of Kingstown, one of the finest mansions in Ireland, built in 1823. Pop. (1851) 3091.

MITFORD, MARY RUSSELL, one of the most successful delineators of English rural life, was the only child of a physician, and was born at Alresford in Hampshire in December 1786. At the age of ten she was sent to a London boarding establishment. She was placed at the same time under the private tuition of Miss Rowden, a lady who was an indefatigable writer of verses, was fond of going to the play, had already educated Lady Caroline Lamb, and was yet destined to educate "L. E. L." and Fanny Kemble. Under such a governess Miss Mitford became inspired with a passion for poetry and the drama. She pored over the tragic authors of France, and devoted to Shakspeare and his great contemporaries. In a short time her own fancy was quickened, and she produced within two years three volumes of juvenile poetry, which were afterwards published, and received a grave censure from the *Quarterly Review*. At the age of fifteen Miss Mitford left the boarding-school and returned home. Her father, a good-natured spendthrift, was now squandering the last remains of a competent fortune. The gaining of a Chancery suit soon afterwards brought him to bankruptcy, and left him a burden in the hands of his daughter. She was now forced to adopt literature as a profession, and commenced to write for the stage. Her first successful drama, the tragedy of *Julian*, was per-

Mitchell
||
Mitford.

Mitford. formed at Covent Garden in 1823. About this time also, in some happy hour, she thought of describing the rural scenes and simple inhabitants in the place of her residence, the small hamlet of Three-Mile-Cross, near Reading. Her fresh and genial sketches appeared in the *Lady's Magazine*, under the title of "Our Village," and attracted general attention. They were published in a volume in 1824; and were afterwards continued until, in 1832, they had filled four other volumes. Meanwhile Miss Mitford had been diversifying such light and congenial occupation with the severe task of dramatic composition. Her tragedies *Foscari* and *Rienzi* were acted with success,—the former at Covent Garden in 1826, and the latter at Drury Lane in 1828. She was now in the enjoyment of a full reputation. It was the custom among young writers to try to catch the tone of her simple rustic sketches. Her cottage of Swallowfield, in the hamlet of Three-Mile-Cross, was visited by the highest and the most accomplished in the land. Yet, necessity compelled her to ply her pen under much ill health and discomfort. In 1838 a pension from government alleviated her cares, but did not slacken her industry. She continued to engage in new literary enterprises, to publish corrected editions of her former works, and to treat her friends with great affection and sweetness of temper, till death closed her career in January 1855.

Miss Mitford also wrote *Atherton and other Tales; Country Stories; Belford Regis; Lights and Shadows of American Life; Recollections of a Literary Life; Tales for Young Persons; Charles the First, a Tragedy*, and other dramatic works.

MITFORD, William, author of a *History of Greece*, was the eldest son of John Mitford of Exbury in Hampshire, and was born in London in 1744. He studied at Queen's College, Oxford; but he showed no taste for any branch of knowledge except Greek, and left the university without a degree. His legal studies at the Middle Temple were becoming equally unsatisfactory, when the death of his father, in 1761, transferred the family estate into his hands, and rendered it no longer necessary that he should adopt a profession. He therefore fixed his residence at his country seat, and turned his attention from the hard details of law to his favourite Greek authors. In 1769 Mitford, entering as captain into the South Hampshire Militia, became acquainted with Gibbon, who was major in the same corps. His intercourse with the future historian, whose brain was then teeming with literary projects, gave form, and perhaps origin, to his purpose of writing a history of Greece. The first volume of this great work appeared in 1784, and the four remaining volumes followed in 1790, 1797, 1808, and 1818, respectively. The increasing infirmities of age prevented the historian from carrying his narration of events beyond the death of Alexander the Great. Meanwhile he had successively represented in Parliament Newport in Cornwall, Bexalston, and New Romney. He had also been appointed professor of ancient history in the Royal Academy. His death took place at his hereditary seat in 1827. An edition of the *History of Greece*, with a Life of the author by his brother, Lord Redesdale, was published in 10 vols. 8vo, London, 1829. The other works of Mitford are,—*An Inquiry into the Principles of Harmony in Languages, and of the Mechanism of Verse, Modern and Ancient*, 8vo, London, 1774; and *A Treatise on the Military Force, and particularly the Militia of this Kingdom*, 8vo.

Previous to the publication of the great historical works of Grote and Thirlwall, Mitford was reckoned the highest authority on Grecian history. More intimate with the original narratives of Thucydides, Xenophon, and Arrian, than any of his predecessors, he discovered much that was new concerning the events and political questions of ancient Greece. Some of his most manifest faults are a cum-

brous style, a deficiency in reflective power, and an occasional dullness in narration. Worse than all these, however, is that obstinate prejudice which invariably leads him to advocate tyranny and to misrepresent democracy.

MITHRIDATES, the name of several kings of Pontus, of whom the most distinguished was *Mithridates VI.*, surnamed Eupator, and usually styled "The Great," King of Pontus, who succeeded his father, Mithridates V., at the age of eleven, about 120 B.C. His reign began amid daring conspiracies, which summoned up prematurely his great tact and intrepidity. Afraid of being poisoned by his treacherous subjects, he followed the practice of swallowing antidotes, until his frame became thoroughly fortified against the action of the most deadly drugs. The more open attempts against his life he baffled by incessant activity. There was no warlike exercise in which he did not engage, and none in which he did not excel. He was also a keen and daring hunter, pursuing his sport into distant and desolate regions, disturbing the lair of the most savage animals, and sleeping on the ground under the most inclement skies. Under such a thorough training, he acquired an iron strength, great agility, a stature almost gigantic, and a spirit indifferent to the presence of any danger. His mind meanwhile was not neglected. He studied with success the physics and philosophy of that age, and cultivated his mind with so much diligence, that he is said to have acquired the languages of no less than twenty-five of the neighbouring nations. At the age of eighteen Mithridates began to govern in his own person. One of his first public acts, it is said, was to render his claim to the throne undisputed by the assassination of his mother and brother. He then directed the entire strength of his kingdom to foreign conquest. Leading his armies eastward along the shore of the Euxine, he conquered Lesser Armenia, Colchis, and other barbarian kingdoms. The wild Scythians of the Tanais, who had dared the might of so many conquering kings, were compelled to submit to his yoke; and his generals being then entrusted with the command of his armies, extended his conquests as far as the River Tyras (*Dniester*), and exacted tribute from the Tauric Chersonese. Shortly afterwards he seized upon the sovereignty of Bosphorus, left vacant by the death of Parisades.

With his strength and resources thus augmented, Mithridates formed the design of wresting all the Asiatic states from the powerful grasp of Rome. Cautiously making his preparations, he first travelled in disguise through Asia Minor, and employed his intimate knowledge of the different languages of that country in ascertaining from the inhabitants the state of their defences and their feelings towards their Roman masters. He then formed an alliance with the Parthians and Iberians, and married his daughter to Tigranes, the powerful King of Armenia. He even entertained the gigantic design of banding together in one great league all the foes of Rome, and of convulsing her sovereignty in all parts of the world by one general shock. His legates accordingly travelled as far as the pillars of Hercules, negotiating with the rebel Marsians and every people and predatory band that were up in arms against the Romans. Before these preparations were completed he became involved in a war with his nephew Ariarathes, King of Cappadocia, who was an ally of the Romans. Ariarathes fell in battle, and Mithridates placed his own son upon the vacant throne. Rome, however, interfered, and seized the Cappadocian crown for Ariobarzanes, a creature of her own. Mithridates succumbed for a time; but about 90 B.C. he openly attacked and deposed the puppet of the Romans. At the same period he wrested the sceptre from the young King Nicomedes of Bithynia, another tributary of the Romans. Both the wronged sovereigns laid their cases before the senate of Rome, and were

Mithridates.

reinstalled in their dominions. Mithridates again submitted; but no long time had elapsed before he was lying at the head of an army of 300,000 waiting for the Romans or their allies to strike the first blow. He did not wait long. Nicomedes, at the instigation of the Romans, invaded Pontus. Mithridates then poured his troops into Cappadocia, and in a short time overran and subdued the whole country. As speedily did his generals Archelaus and Neoptolemus prostrate the might of Nicomedes in a great battle on the banks of the Amnias, and wrest Bithynia from the remnants of his army. The neighbouring states, eagerly hailing the outbreak of a war that seemed likely to free them from the insatiable rapacity of their Roman oppressors, raised the standard of revolt. All the cities of Asia Minor, with a few exceptions, flung open their gates to the victorious King of Pontus, and he marched westward without opposition to the shores of the Ægean Sea. Lesbos, Delos, Eubœa, and the islands of the Cyclades, were next subjected to his sway, and even Athens was betrayed into the hands of his general Archelaus. In the height of his triumph Mithridates repaired to Pergamus, and abandoned himself to luxury and pleasure. It was then that he issued a decree for the extermination of all the Roman citizens in Asia Minor. With an eager promptitude the vengeful natives obeyed the order; and the massacre of 80,000, or, according to some, of 150,000 Romans, cut off Mithridates from all chance of reconciliation with his powerful foes. About the middle of 87 B.C. he was roused to his former activity by the news that a Roman army under Sylla was approaching Greece. He immediately despatched Taxiles with an immense force to co-operate with Archelaus. In the following year, however, the news arrived that Athens had been captured, and that his troops had been routed at the battle of Chæronea. With unslackened perseverance he equipped another army of 80,000, and sent it under the command of Dorylaeus to the scene of conflict. But the tide of fortune was running against him; and in 85 B.C. his position had become critical. The time-serving Asiatics, estranged by his growing misfortunes, were rising in revolt around him, and assassinating the tetrarchs he had placed over them. An army sent by the Marian party at Rome had invaded Asia Minor, had defeated a large force under his son Mithridates, and was pursuing himself from place to place. About the same time he received the intelligence of the almost utter annihilation of his Grecian troops at Orchomenus. Almost his only resource, therefore, was a treaty of peace. This, after some difficulty, he purchased from Sylla in 84 B.C. at the expense of 2000 talents, 70 ships, and all the territories he had wrested from the Romans.

In spite of this treaty, Mithridates knew well that nothing less than his complete humiliation would satisfy his haughty enemies, and therefore he resolved to prepare for the worst. Several years were spent in building navies, in collecting magazines of arms and provisions, in recruiting his army, and in gathering hordes of mercenaries from every quarter both in Asia and in Europe. He equipped his troops with Roman arms, and attempted to infuse into them the magnanimous Roman valour by subjecting them to the severe Roman discipline. He even entered into an alliance with Sertorius the great Marian general in Spain. After such preparations he was bold enough, on the death of Nicomedes III. in 74 B.C., to lay claim to the vacant throne of Bithynia. He then burst into that country with a mighty army, swept through it without encountering opposition, and overwhelmed the forces of Cotta the prætor under the walls of Chalcedon. Marching then into Mysia, he sat down before Cyzicus, and invested that city by land and sea. Thither Lucullus the Roman general followed him. For some time the two armies lay encamped near each other without meeting in any general engagement. At last Mithridates,

unable to provide for so large an army in so narrow a territory, was forced to raise the siege and to commence a retreat towards the west. Lucullus then hovered about his rear, threw his army into confusion, and took many prisoners. With great difficulty Mithridates embarked his shattered forces and set sail homewards. On the way a storm sunk his fleet, and he arrived in his own dominions with a fragment of that magnificent army with which he had set out. Yet Mithridates still retained his invincible energy, and that soon supplied him with another army. By the spring of 72 B.C. he had organized a large force of his own subjects, of Scythians, and of Parthians, and awaited the arrival of Lucullus in an impregnable position among the mountains at Cabira. Lucullus arrived, but found that his enemy had learned a lesson from former misfortunes, and that he was resolved to act merely on the defensive. He attempted to dislodge him, but was repulsed with great loss. In a short time he discovered that his provisions were effectually cut off, and that want was beginning to lay waste his camp. At this crisis an accident saved him. The forces of Mithridates, compelled by a misfortune to shift their camp, were struck with a sudden panic. A headlong flight ensued, and their ranks were cut to pieces and scattered over the whole country by the pursuing Roman cavalry. The King himself, after braving many dangers in his desperate attempts to rally his troops, fled to the kingdom of his son-in-law Tigranes, and left all his dominions in the power of Lucullus.

In 69 B.C. Tigranes mustered a large army to vindicate the cause of his father-in-law, and at the same time to defend his own territories against the invading Romans; but risking, in opposition to the advice of Mithridates, a pitched battle at Tigranocerta, he was defeated by Lucullus with great slaughter. The ensuing winter was spent by Mithridates in equipping a select force of 70,000 with Roman armour, and in inuring them to Roman discipline. In the summer of 68 B.C. he commenced to harass the advance of Lucullus into Armenia by cutting off his foraging parties, and by galling his rear with bodies of skirmishers. At length he was brought to a general engagement near Artaxata, and suffered a severe defeat. But no sooner had the enemy marched into Mesopotamia to lay siege to the strong fortress of Nisibis, than Mithridates betook himself to Pontus at the head of 4000 chosen troops, and commenced a sudden and daring guerilla war. Garrison after garrison was surprised and wrested from the Romans; his old soldiers rallied round his standard; the army under Fabius, the lieutenant of Lucullus, was cut to pieces; and when winter suspended the contest, Triarius was the only Roman commander who was capable of offering any effectual resistance. With him Mithridates prepared to engage in the spring of 87 B.C. A pitched battle soon took place, in which the Romans, after an obstinate struggle, fled, leaving their camp in the hands of the enemy and 7000 of their officers and private soldiers lying dead on the field. This defeat, the most disastrous blow that had fallen upon Rome for many years, left the greater part of Pontus in the hands of Mithridates.

The King of Pontus was engrossed with the re-organization of his government when Pompey the Great arrived in Asia in 66 B.C. to supersede Lucullus. That able general immediately formed an alliance with the Parthian king, and thus rendered it necessary for Tigranes to keep his troops for the protection of his own dominions. Mithridates was accordingly left to meet his great antagonist all alone. At first he tried negotiation, but scorned to stoop to the conditions that were offered to him. He then placed himself at the head of 32,000 well-disciplined troops, and resorted to his former plan of defensive warfare. For some time he attended the movements of the Romans, intercepting their provisions, destroying their foragers, and baffling

Mithridates.

Mitrowicz all their attempts to force him to a general engagement. At length desperation drove Pompey to attack him by night on the banks of the Euphrates. An accident spread a panic through the king's forces; in a few moments there was a general flight; and the greater part of the Pontine army were either slain by the Romans or drowned in attempting to cross the river. Mithridates himself, at the head of a few horsemen, cut his way through the legions of the enemy, and escaped to the border stronghold of Synoria. Thence he hastened with a considerable body of troops to take refuge in Armenia. But dread of the Romans prevented Tigranes from giving him any countenance. The only retreat now left to him was the kingdom of Bosphorus, over which his son Machares reigned. Thither, therefore, he directed his course by forced marches through the country of Colchis, until he arrived at Dioscurias. Assured then that he was beyond the reach of Pompey, he halted, and passed the winter enlisting troops and equipping a fleet for the remainder of his journey. In 65 B.C. he continued his march through the midst of the most savage tribes, exciting the opposition of some and the enthusiastic admiration of others, yet pressing onwards with resistless constancy. At length he arrived at Panticapæum, the capital of the kingdom of Bosphorus, and found that his son Machares, who had formerly sent in his submission to the Romans, had put an end to his life on hearing of his approach. Mithridates accordingly seated himself in the vacant throne. His newly-acquired power was far beyond the reach of the grasping tyranny of Rome, and he might now have rested from that disastrous struggle in which he had been engaged for the last twenty-six years. Yet hardly had he organized his government, when he conceived the daring plan of marching at the head of a large army round the north and west coasts of the Euxine, of rallying round his standard all those barbaric tribes who cherished a deadly enmity towards Rome, of bursting with an overwhelming horde into the Roman possessions, and of even penetrating into Italy and striking at the Eternal City itself. With all possible speed he set himself to muster the strength of his kingdom, and soon saw himself at the head of an army of 36,000, supported by a considerable fleet. However, as the desperate nature of the coming expedition began to be generally known, the soldiers began to falter in their allegiance. This growing disaffection speedily swelled into open revolt, through the intrigues of Pharnaces, the king's own son and heir. In vain did Mithridates attempt to awe his troops into obedience, and to excite filial regard in his son. He was forced to flee for his life into a strong fortress. There he resolved to die, that he might not fall alive into the hands of his remorseless subjects. He tried to poison himself; but his iron constitution, even at the age of sixty-eight, was proof against the deadly drug, and he was compelled to die on the sword of a faithful Gallic mercenary.

Mithridates is described by Peterculus as "a man who can neither be mentioned nor passed over without caution; most valiant in war, unrivalled for valour,—renowned at one time for success, at all times for magnanimity,—a general in council, a soldier in action, and a very Hannibal in his hatred of the Romans."

MITROWICZ, a town of the Austrian dominions, in the Slavonian military frontier, on the left bank of the Save, 24 miles S.S.W. of Peterwardein. The town possesses a castle, several churches and schools, and is the headquarters of the Peterwardein regiment. It has also some Roman remains, and is supposed to occupy the site of the ancient *Sirmium*. Pop. 5500.

MITWEIDA, a manufacturing town of Saxony, in the circle of Zwickau, on the Zschopau, 35 miles S.E. of Leipsic. It produces woollen, cotton, and linen stuffs, and is provided with large bleachfields. Pop. 7012.

MITYLENE, or MIDULLU (the ancient *Lesbos*), an island of the Grecian Archipelago, belonging to Turkey, and lying off the west coast of Asia Minor. It is about 45 miles in length by 30 in extreme width, and contains an estimated area of 168,320 acres. The island is traversed by wooded hills, beautifully diversified by plains and valleys; while the two inlets Ports Culoni and Lero extend into the land for several miles, almost severing the island into two portions. The soil is excellent, and the climate salubrious; but want of proper irrigation has much impeded farm operations. The principal articles produced are,—olive oil, silk, cotton, fruit, and indifferent wine. Grain is not grown in sufficient quantity to supply the home consumption. The principal towns are Castro, on the S.E. coast, with 10,000 inhabitants; Molivo; and Culoni. Mitylene suffered much in the Greek war of independence, in the course of which it lost nearly the half of its inhabitants. Pop. 40,000, the majority of whom are Turks. (See *LESBOS*.)

MNEMONICS, or MNEMOTECHNY (from *μνήμη*, *memory*, and *τέχνη*, *art*), is the art of improving the memory by artificial means. Its discoverer is said to have been Simonides the poet, who flourished about B.C. 500. The story is, that he had been employed by Scopas, a rich Thesalian nobleman, to compose a song in commemoration of a victory gained by him at the Olympic games. This was sung at a banquet given in honour of the occasion; but Scopas was so displeased that part of it was occupied with the praises of Castor and Pollux, that he said he would pay the poet only one-half of the stipulated reward, as he had received but one-half of the praise, and that he might, if he chose, apply to his friends the Tyndaridæ for the remainder. Shortly after this, and while yet at the feast, a message was brought to Simonides that there were two young men at the gate very anxious to speak to him. When he went out he found no one; but while engaged in the search, the house he had just left fell down, killing Scopas and all that were with him. The bodies were so mutilated that they could not be recognised; but Simonides, by calling to mind the place that each had occupied at the feast, was able to distinguish them; and hence his attention was first directed to the important aid afforded to memory by the observation of material objects.

This art was practised and recommended by more than one of the ancients, amongst whom is Cicero, who says,—"There can scarcely be any one of so acute a memory that he can retain the order of words and sentences without observing and associating them with material objects; nor, on the other hand, is there any one of so dull a memory as not to receive aid from the use of this plan, . . . those things being most fixed in the mind which have been given to it and impressed upon it by sense." In modern times the subject of Mnemonics does not seem to have generally received that amount of attention which its importance demands. Various works have indeed been written upon the subject, and various systems advocated, but none of them have met with any great degree of success. This is doubtless chiefly to be accounted for from the fact that the propounders of the various systems have had more in view the exhibiting of mere feats of memory, than the applying of the principles of the art to matters of real value and importance. What Lord Bacon says of the systems of his time is still in a great measure true, that those "now in use are but barren and useless. For immediately to repeat a multitude of names or words once repeated before . . . I esteem . . . no more than rope-dancing, antic postures, and feats of activity; and, indeed, they are nearly the same things, the one being the abuse of the bodily as the other is of the mental powers; and though they may cause admiration, they cannot be highly esteemed."

The value of any system of Mnemonics must necessarily depend upon the extent to which it is based upon the prin-

Mnemonics.

Mnemo-
nics.

ciples and laws of memory. This term, as it is commonly used, implies both the power of retaining and of recalling whatever may have already been before the mind. These powers vary greatly, not only in different, but even in the same individual,—some having a good retention but a bad recollection, while others have a good recollection but a bad retention. Though thus apparently different in character, they yet seem in reality to be the result of one general principle; a good or a bad retention, as well as a good or a bad recollection, being alike and entirely dependent upon the laws of association. Indeed, so far as retention is concerned, it is held by many philosophers that there are no individual differences,—that whatever has once been the object of consciousness is ever thereafter retained, and that its being or not being recalled depends entirely upon association. In support of this doctrine we have numerous instances of persons recollecting, in the delirium of a fever, things that in ordinary circumstances had long been beyond the power of recall. Thus there have been instances of persons in such a state talking fluently in a language, that of their childhood, which they had long forgotten. In dreaming, too, many things are suggested to our minds which we know must be resuscitated ideas, even though we cannot recognise them as such.

Memory, then, depends upon what are by philosophers termed the laws of mental association, suggestion, or reproduction. The great law of association, and that to which probably all the others may be referred, is that of contiguity. Ideas that have been in the mind together, or in close succession, ever after manifest a tendency to recall or reproduce each other. As a general rule, we find this tendency most marked, as indeed was to be expected, in persons with few ideas among the ignorant and uneducated. Shakspeare's Mrs Quickly is an admirable instance of this, as she narrates with amazing minuteness the various incidents that happened at the time when Sir John Falstaff had made her a promise of marriage. Where, however, the mind has been actively at work, and has stored up a great number of ideas, those that have been frequently before it have become associated in a variety of ways with numerous other ideas. Such then have the power of suggesting, not only ideas that may have been associated with them at any particular time, but also those that may have been connected with them at various times. Were in such cases every idea to bring before the mind all with which it had at any time been connected, the result would be endless confusion. Instead, therefore, of a host of ideas, we find that generally only one or a few rise before consciousness. That some rather than others are selected and brought before the mind depends upon a variety of circumstances,—such as their affinity to immediately preceding ideas or to the general habits of thought of the individual, their recentness or abstractedness from other ideas, or their affinity to the suggesting idea, arising from the frequency or length of time they may have been associated with it.

An idea, however, may give rise to other ideas, with which it had never previously been associated. Thus, Hannibal may immediately suggest Napoleon, though they may have never been previously together in the mind. This is done by means of a third idea common to both: among the various ideas that have been associated in the mind with Hannibal, one is that he crossed the Alps with an armed force; but this latter idea has been also associated in the mind at another time with Napoleon, and hence he is immediately suggested. The common idea is here evident; but frequently it does not come before consciousness, though in every case its influence may be traced. This is what is called the law of *similarity*, though in reality it seems to be merely a modification of that of contiguity,—the one idea suggesting the other, not directly, but by means of a third idea common to both. To this same

principle of contiguity, we think, may also be referred that tendency of the mind to proceed from one idea to its contrary,—as from virtue to vice, from light to darkness, from riches to poverty,—there being in every such case an intermediate idea common to both, of which the one is an abundance and the other a deficiency. It is this principle of association by similarity that we find to predominate in men of genius, as poets, artists, philosophers, and others. It was this that led Sir Isaac Newton to see the one principle of attraction governing alike the falling of an apple and the revolution of a world. Though depending chiefly on natural endowment, it is also to a great degree capable of cultivation.

Another principle of association is that of a part suggesting its whole, or a whole one or more of its parts. Most of our ideas are made up of a number of others. The paper I write upon is, in my mind, made up of ideas of form, colour, smoothness, &c. The mind has the power of analyzing and reducing such an idea to its component parts, so that it becomes merely a number of associated ideas. Any one of these may, in accordance with the ordinary principles of reproduction, suggest the whole idea, or the whole idea may suggest one or more of its parts. Paper may immediately suggest to the mind whiteness, and this whiteness may suggest another, or a number of other things, of which it is likewise a property. In like manner, a word may be resolved into its component parts or syllables, any one of which tends to suggest other words of which it forms a part. Thus, one word may suggest another word or words having the same initial or terminal syllables; and hence the rhythmical terminations of the lines in poetry make it much more readily remembered than prose, and the alliteration so frequent in proverbs renders them pleasing to the memory and easy of recall. The principles of mental association are well illustrated by Coleridge in the following passage:—"Seeing a mackerel, it may happen that I immediately think of gooseberries, because I at the same time ate mackerel with gooseberries as the sauce. The first syllable of the latter word being that which had co-existed with the image of the bird so called, I may then think of a goose. In the next moment the image of a swan may arise before me, though I had never seen the two birds together. In the first two instances, I am conscious that their co-existence in time was the circumstance that enabled me to recollect them; and equally conscious am I that the latter was recalled to me by the joint operation of likeness and contrast. So it is with cause and effect; so too with order."

It follows naturally, as a principle of contiguity, that, as a general rule, the closer ideas are brought together in the mind, the more strongly will they be associated, and the greater will be their power of reproducing each other. When an interval takes place between ideas brought before consciousness for the purpose of being associated together, there is ever a tendency of irrelevant ideas to spring up in the mind and interfere with their adhesion. This is especially marked when our circumstances are such as to readily suggest ideas to our mind apart from those we wish to impress upon it. Hence the importance to memory of sound health and a mind free from anxieties. Sensations exercise an important influence in the direction of our thoughts, and in giving rise to new trains of ideas; and indeed it seems highly probable that there are conditions of body, even beyond the pale of consciousness, that exert an important influence in this respect.

Memory, probably more than any of the other faculties of the mind, is dependent on the physical condition of the body. We may smile as we read in old works on Mnemonics of "plaisters to prevent a decay of memory," "a powder for the memory," or "a perfumed apple for comforting the brain and memory;" but these all indicate a belief in the dependence of memory upon the physical condition of the body; and we find in the present day so high a medical

Mnemo-
nics.

Mnemo-
nics..

authority as Sir Benjamin Brodie supporting the same opinion when he says, "It is possible that by accurate observation the proper means may be discovered of preserving that temperament of the brain which is favourable to memory, and of remedying the disorders of that temperament."

Some ideas are much more easily retained and recalled than others,—those presented to us by the senses occupying in this respect the chief place. The mind is first awakened to consciousness by sensations, and these are ever the most easy of retention or reproduction. Of all the senses, that of sight is the one that furnishes the mind with most ideas, and these are always the most vividly and lastingly impressed upon it. In cases of loss of memory we frequently find that, after all other sensational ideas have been lost, those of sight may still be retained. Thus, a sentence when spoken may convey no idea to the mind, while the same when written may be readily understood; and one may be able to write what, from mere obliviousness of the sound, he is unable to speak. Most persons, too, may have experienced, when in doubt as to the correct spelling of a word, that they have frequently been put right by recalling to the mind the appearance of the word, or by writing it down. When two or more of the senses are employed in impressing a thing upon the mind, the advantage is greater than if one only were employed. Every schoolboy knows that he learns his lesson much more quickly by repeating it aloud, for in this case he has both the ear and the eye to assist him; and next to the eye the ear is, as an aid to memory, the most valuable of the senses.

We have been thus minute in explaining the principles of memory, because, as already said, it is only in accordance with these that memory can be judiciously improved; and further, because we believe that no one system of Mnemonics can be equally beneficial in every case. Mnemonics is the art of associating in the mind things difficult with things that are easily remembered, so that the former may be retained and recollected from being associated with the latter. Memory, however, varies greatly in different individuals, some manifesting the greatest facility in remembering places, others events, others names, and so on, according to the species of memory that each may have received from nature, or acquired by previous education. In each particular case it is of importance to know where the strongest points of memory lie, and to employ these in the assistance of the weaker.

One great principle of mental association is to bring together as nearly as possible in the mind ideas that we wish to connect, as by this means we guard against irrelevant ideas intervening that would injuriously affect their adhesion. It is upon this principle that what is called the Hamiltonian system of teaching languages is constructed,—that, namely, of bringing the foreign word and the English equivalent into the nearest possible proximity.

Another important principle that, from the foregoing considerations, we arrive at, is that of associating an abstract idea that we wish to remember with a sensational. Most persons must have observed, that in passing along a road which they had formerly travelled in the company of a friend, the particulars of a conversation in which they were then engaged are frequently suggested by the objects they meet with. They recollect that in such a place a particular subject was started, and as they pass the various houses, plantations, rivers, &c., on the way, the parts of the subject under discussion when these were last seen are immediately suggested to the mind. The same result will be obtained, though less perfectly, by merely bringing the various objects before the mind in imagination—the ideas associated with each will spring up. We may in this way connect ideas that we wish to remember with the public buildings of a town, the houses of a street, or the furniture of a room, and by going over these objects in reality or in imagination, the ideas formerly associated with

them will spring up. This is the system of Mnemonics as recommended and practised by Cicero, Quintilian, and others.

Another principle, even more important than the last, because it belongs to a higher and more advanced state of mind, is that of associating what we wish to remember with ideas already in the mind; and according to the familiarity of those ideas will be their value as a means of reproduction. As the mind enlarges and becomes stocked with ideas, we find that suggestion comes to depend more and more upon what are commonly called the laws of similarity or contrast. In reading the account of a battle, for instance, one will best remember it by associating it with another already in his mind, and noting the points of resemblance or contrast. It is the same with other branches of history, with biography, or with more abstract subjects. Hence the great importance of exercise to the memory, by which it is not only strengthened, but by which stores of materials are laid up with which to associate new acquirements. A law prevails in the mental world similar to that of chemical attraction in the material,—a law by which ideas with certain affinities are attracted to each other and all others repelled.

It may be considered necessary, before concluding the present article, to say something of the means commonly adopted by Mnemonicians for performing their great feats of memory. For this purpose a number of rooms are selected, the walls and floor of which are each divided in imagination into 9 equal parts or squares, 3 in a row. On the front wall (that opposite the entrance) of the first room are the units, on the right hand wall the tens, the left hand the twenties, the fourth wall the thirties, and the floor the forties. Nos. 0, 10, 20, and 30 each find a place on the roof immediately above their respective walls, while 40 is placed in the centre of the roof. One room will thus supply 49 places, and with 10 rooms we may have 500 places, all save one. Having fixed these in the mind so that the exact position of each place may be readily ascertained it is then necessary to associate with each of them a certain familiar object, so that, on the object being suggested, its place may be recalled; or when the place is before the mind, its object may immediately spring up. When this has been done thoroughly, the objects can be run over in any order from beginning to end, from end to beginning, or the place of any one can at once be given. It will also facilitate reference if the objects are arranged according to a certain plan. Each room may be devoted to one class of objects, the subdivisions of which may occupy the various places on the walls and floor, on the same principle as a librarian arranges the books of his library, or a naturalist the objects in his museum. All that is further necessary is to associate the subjects that we wish to remember with the objects in the various places, by which means they are readily remembered, and can be gone over in any order. In this way some are able to repeat in any order several hundred disconnected, or even unmeaning, words or ideas, after having once heard them.

To remember dates or sums, letters are substituted for the figures, and formed into words. Thus:

$t, n, m, r, l, d, c, h, g, q, b, h, v, w, p, f, s, x, z.$
1, 2, 3, 4, 5, 6, 7, 8, 9, 0.

The vowels are of no value, but are merely introduced between the consonants to form words. In this way *tin*, *tone*, *ten*, *tun*, &c., stand for 12; *tins*, *tens*, &c., for 120; and *tabled* for 1856. This last branch of Mnemonics, which we cannot enter upon at greater length, will be found fully treated of in Dr Grey's *Memoria Technica*, and exemplified in history, geography, astronomy, &c.

MNEMOSYNE (*μνημοσύνη*, *memory*), according to fabulous history, one of the Titanides, and the daughter of Uranus, who married Zeus, and became the mother of the Muses. (Hesiod. *Theog.*, 54, 915; and Cicero, *De Natura*

syne.

Moia Isle
||
Moabites.

Deorum, iii. 21.) A statue was erected to her honour at Athens; and, according to Pausanias, she had a sacred well and throne near the Trepheonian oracle. The origin of this fable of the maternity of the Muses had doubtless a relation to the important part which the faculty of memory performs in the development of art and in the growth of science.

MOA ISLE, in the eastern seas, is situated off the eastern extremity of Timor, and intersected by the 128th degree of east longitude. Lat. 8. 20. S.

MOABITES, a tribe descended from Moab, the son of Lot, and consequently related to the Hebrews. (Gen. xix. 37.) Previous to the exodus from Egypt, the Moabites, after expelling the original inhabitants, called *Emims* (Gen. xiv. 5; Deut. ii. 11), had possessed themselves of the region on the E. of the Dead Sea and the Jordan, as far N. as the River Jabbok. But the northern portion of the territory, extending from the Jabbok to the Arnon, had passed into the hands of the Amorites, and hence the valley and river Arnon constituted the northern boundary of Moab. (Numb. xxi. 13; Judg. xi. 18; Josephus, *Antiq.* iv. 5, 1.) The Moabites, on the advance of the Hebrews towards Canaan, fearing the numbers that were marching around them, gave evidence of a spirit of hostility (Deut. xxiii. 3); and their king, Balak, hired Balaam to utter prophetic curses, which were converted into blessings in his mouth (Num. xxii., *sq.*) The Gadites now took possession of the northern portion of the territory, which the Amorites had wrested from the Moabites, while the Reubenites occupied the south. (Num. xxxii. 34; comp. Josh. xiii.)

We see the first hostilities breaking out in the beginning of the period of the Judges, when the Hebrews had been for a long time tributary to the Moabites, but threw off their yoke under Ehud. (Judg. iii. 12-30.) Peace and friendship, however, were afterwards restored; and Moab appears often to have afforded a place of refuge to outcasts and emigrant Hebrews. (Ruth i. 1; comp. 1 Sam. xxii. 3, 4; Jer. xl. 11; Isa. xvi. 2.) After Saul had waged successful war against them (1 Sam. xiv. 47), David made them tributary (2 Sam. viii. 2, 12; xxiii. 20); and the right to levy this tribute seems to have been transferred to Israel after the division of the kingdom (2 Kings i. 1, iii. 4; comp. Isa. xvi. 1). To avenge an invasion of their territory, in which the King of Judah had taken part, the Moabites formed a powerful confederacy with the Ammonites, Edomites, and others, who marched in great force into Judæa, and having formed their camp at Engedi, they fell out among themselves and destroyed each other.

The most natural explanation of the recovery by Moab (Isa. xvi.) of the territory between the Arnon and the Jabbok, and respecting which Jewish history is silent, is that of Reland (*Palestina*, p. 720), Paulus (*Clavis*, p. 110), and Rosenmüller (*in loc.*), that, after the carrying away of Reuben and Gad into captivity, the Moabites occupied their territory. Still later, under Nebuchadnezzar, we see the Moabites acting as the auxiliaries of the Chaldeans (2 Kings xxiv. 2), and beholding with malicious satisfaction the destruction of a kindred people (Ezek. xxv. 8-11); yet, according to an account in Josephus (*Antiq.* x. 9, 7), Nebuchadnezzar, when on his way to Egypt, made war upon them, and subdued them, together with the Ammonites, five years after the destruction of Jerusalem. On the other hand, there is no authority in any one ancient account for that which modern historians have repeatedly copied from one another,—viz., that Moab was carried into exile by Nebuchadnezzar, and restored with the Hebrews under Cyrus.

Continual wars and contention must have created a feeling of national hostility between the Hebrews and the Moabites; and this feeling manifested itself on the part of the Hebrews in bitter proverbs and in the denunciations of their prophets. Moreover, the subjection of Moab finds a place in every ideal description of splendid wars and golden

ages predicted for Israel (Isa. xi. 14, xxv. 10; Ps. lx. 8; Ps. lxxxiii. 6).

Moabites.

After the exile an intimate connection between the two nations had found place by means of intermarriages (Ezra ix. 1, *sq.*; Neh. xiii. 1), which, however, were dissolved by the theocratic zeal of Ezra. The last notice (chronologically) of the Moabites which occurs in Scripture is in Dan. xi. 41, which contains an obscure intimation of the escape of the Moabites from the overthrow with which neighbouring countries would be visited; but Josephus, in the history of Alexander Jannæus, mentions the cities between Arnon and Jabbok under the title of cities of Moab. (*Antiq.* xiii. 15.) Thenceforth their name is lost under that of the Arabians, as was also the case with Ammon and Edom. At the time of Abulfeda, Moab proper, S. of the Arnon, bore the name of Karak, from the city so called; and the territory N. of the Arnon, that of Belka, which includes also the Ammonites. Since that time the accounts of that region are uncommonly meagre; for, through fear of the predatory and mischievous Arabs that people it, few of the numerous travellers in Palestine have ventured to explore it. (For scanty accounts, see Büsching's *Asia*, pp. 507, 508.) Seetzen, who in February and March 1806, not without danger of losing his life, undertook a tour from Damascus down to the south of Jordan and the Dead Sea, and thence to Jerusalem, was the first to shed a new and altogether unexpected light upon the topography of this region. He found a multitude of places, or at least of ruins of places, still bearing the old names; and thus has set bounds to the perfectly arbitrary designations of them on the old charts. From June to September 1812, Burckhardt made the same tour; and the details of this journey, which are contained in his *Travels in Syria and the Holy Land*, 1822, threw much light upon the ancient topography and present condition of the lands of Moab and Edom. The accounts of Seetzen and Burckhardt give the substance of all the information which we even yet possess concerning the land of Moab. The *Travels* of Irby and Mangles in 1818, and Legh's Supplement to Dr Macmichael's *Journey from Moscow to Constantinople*, 1819, furnish the most valuable additions which have as yet been obtained to the information of Seetzen and Burckhardt. More recent travellers in Palestine have added little to our previous knowledge of the land of Moab.

From the sources already alluded to we learn that in the land of Moab, which lay to the E. and S.E. of Judæa, and which bordered on the E., N.E., and partly on the S. of the Dead Sea, the soil is rather more diversified than that of Ammon; and, where the desert and plains of salt have not encroached upon its borders, of equal fertility. There are manifest and abundant signs of its ancient importance. "The whole of the plains are covered with the sites of towns on every eminence or spot convenient for the construction of one; and as the land is capable of rich cultivation, there can be no doubt that the country, now so deserted, once presented a continued picture of plenty and fertility." (Irby and Mangles, p. 378.) The form of fields is still visible, and there are remains of Roman highways, which are in some places completely paved, and on which there are milestones of the times of Trajan, Marcus Aurelius, and Severus, with the numbers of the miles legible upon them. It was in its state of highest prosperity that the prophets foretold that the cities of Moab should become desolate, without any to dwell in them; and accordingly we find, that although the sites, ruins, and names of many ancient cities of Moab can still be traced, not one of them exists at the present day as tenanted by man.

MOAT. See FORTIFICATION.

MOBILE, a seaport-town of the United States of North America, capital of a cognominal county in the state of Alabama, is situated on the right bank of Mobile River,

Mobile. immediately above its entrance into the bay of the same name, 165 miles E. by N. of New Orleans; N. Lat. 30. 41., W. Long. 88. 1. The site of the town is a sandy plain, slightly elevated above the river, and affording a sufficient fall for the purposes of drainage; while in its vicinity are extensive pine hills, resorted to in summer for their healthy exposure. The city itself is laid out in streets, crossing each other at right angles, but which, excepting in the mercantile quarter near the wharves, are rather incompactly built. Most of the wider streets have been tastefully planted with trees; and the houses are copiously supplied with excellent spring water. For many years, however, it had the unenviable notoriety of being one of the most unhealthy places on the Mexican Gulf; and indeed the devastating epidemics of 1819, 1825, 1829, and 1843, gave melancholy evidence of the fact. But subsequently there has been a marked improvement in this respect, owing to the filling up of the neighbouring marshes, and to the introduction of a system of drainage, as well as to greater attention being paid to the sanitary affairs of the town. The public edifices of Mobile are numerous: the chief are the Spring-hill college, founded in 1830, and possessing a library of 7000 volumes; the U.S. marine hospital; and a large new custom-house; besides many charitable and literary institutions. A battery, named Fort Morgan, defends the entrance of the bay, and a lighthouse stands in the same situation. Mobile is by far the most considerable town in Alabama, in regard both to population and commerce, and, after New Orleans, is the greatest cotton market in the United States. Communicating with the interior by the rivers Alabama and Tombigby, its harbour is supplied with the produce of the great cotton plantations of the state with ease, and at a trifling expense; while by railroads it will in a short time be united with the Ohio and the great lakes in the N., and with Georgia in the E. Its harbour may be considered to be the entire Bay of Mobile, which forms an inlet of great extent, and affords secure anchorage. On account, however, of some obstructions of a removable character, ships drawing more than 11 feet cannot reach the city. During the year ending June 30, 1856, the arrivals of shipping at this port amounted to 473,678 tons, of which 301,498 tons were engaged in the coasting trade. The clearances in the same year numbered 312,973 tons only, 98,264 tons of which went coastwise. Of this amount of tonnage about a fourth part belonged to Britain. The imports of Mobile chiefly consist of salt, oats, flour, corn, bacon, whisky, bagging, and railroad iron; but come considerably short in value of the exports, which comprise cotton, timber (rough and manufactured), hides, oysters, rosin, bricks, tar, and pitch. In the following table the total values are given for the years 1853, 1854, and 1856:—

	1853.	1854.	1856.
Imports (foreign) ... L.	163,992	183,854	162,381
Exports do. ...	4,903,419	3,296,792	2,943,362

Of the latter, cotton is the most important, 557,243 bales having been shipped, coastwise as well as to foreign ports, during 1856, = L. 5,389,432. More than the half of this was exported to Britain, and that chiefly in British ships. The next articles in point of value were masts and spars, amounting to L. 35,678, and which were exported chiefly to France for naval purposes. Ordinary rough and hewn timber was exported in the same year to the value of L. 18,889, hides to that of L. 12,208, oysters to L. 11,573, and rosin to that of L. 8331. The manufactures of Mobile are inconsiderable compared with its general trade; and, with the exception of a cotton-mill, employing 180 hands, the factories are all of small dimensions. The prosperity of the city, however, can be better judged of by the valuation of the merchandise and real estate belonging to its inhabitants: in 1840 the total value of these amounted to L. 3,388,986, and in 1850 to L. 3,651,860.

VOL. XV.

The history of the place commences with the French possession of Louisiana. In 1702 Bienville founded the original town of Mobile at the mouth of Dog River, but in consequence of inundations it was removed, nine years afterwards, to its present site at the mouth of the Mobile River. An extensive fortress was built here, and the seat of government permanently fixed. At the peace of 1763 the town passed into the possession of the English. Under the latter its exports comprised indigo, raw hides, tobacco, timber, pecan nuts, and a small amount of cotton. In 1777 Bertram describes Mobile as extending back half a mile from the river, with a few good buildings occupied by the French or emigrants from England, Scotland, Ireland, and the North American colonies. At the close of the American revolution, the Spaniards again came into possession under the general treaty of peace; but on the cession of Louisiana to the United States, the Americans took final possession of Mobile without striking a blow. Pop. (1788) 1468, (1820) 1500, (1840) 12,672, and in 1850, 20,515; of which 12,997 were whites, 715 free coloured, and 6803 slaves; 752 were English and Scotch, 2009 Irish, 552 German, and 303 French. Total pop. in 1855, about 24,000.

MOBILIER, CRÉDIT (*La Société Générale de Crédit Mobilier*), is a bank founded in Paris, under the sanction of a decree of the imperial government, bearing date the 18th of November 1852, and is of such a peculiar design and nature as to deserve a lengthened notice. The name is derived from an intentional contrast with companies known on the Continent as *Sociétés de Crédit Foncier*. These companies, which are in the nature of land banks, advance money on the security of real, or, in the language of continental jurists, *immoveable* property, and raise the money so to be used by the issue of debentures for sums of moderate amount, in some cases for so little as four pounds. The *Crédit Mobilier*, according to its original design, was to obtain money in a somewhat similar way, by the issue of debentures, and to employ the funds so obtained in giving the same aid to the owners, or some of the owners, of *moveable* property, that the companies of *Crédit Foncier* afforded to persons possessed of land. Such aid was not, however, to be given by the new company in what are clearly the simplest ways, by the discount of bills or advances. There were already in France institutions, such as the Bank of France and the *Comptoir d'Escompte*, which aided commercial men by loans in these forms. The *Crédit Mobilier* was to effect a similar object in a mode less direct and more peculiar.

"It is to play," said M. Pereire, one of the original founders of the company, "with respect to the fixed capital employed in industry, a part analogous to that which banks of discount fill with respect to its circulating capital. The first duty of our society," he continues, "is to aid the development of national industry, to facilitate the completion of great enterprises, which, without such assistance, are perfected with so much difficulty." And in language which we give in the original, because the peculiar tone of the language is most characteristic of the temper in which the company has been planned, and can scarcely be preserved in a translation, he remarks,—

"La pensée du *Crédit mobilier* est née de l'insuffisance des moyens de crédit offerts à l'organisation des grandes affaires du pays, de l'isolement où étaient réduites les forces financières, de l'absence d'un centre assez puissant pour les relier entre elles.

"Elle est née du besoin d'amener sur le marché le concours régulier de capitaux nouveaux destinés à aider au développement du crédit public et du crédit industriel ;

"Elle est née de l'exagération des conditions auxquelles se faisaient les prêts sur fonds publics et des difficultés qui en naissaient pour le classement définitif des meilleures valeurs.

Mobilier, Crédit.

Mobilier,
Crédit.

"Elle est née encore du besoin de centraliser le mouvement financier et administratif des grandes Compagnies et notamment des Compagnies de chemins de fer, d'utiliser ainsi, au plus grand avantage de toutes, les capitaux dont chacune dispose successivement, de manière à ménager les ressources communes, aussi bien au profit des Compagnies qu'à celui de leurs nombreux actionnaires.

"Elle est née enfin de la nécessité d'introduire dans la circulation un nouvel agent, une nouvelle monnaie fiduciaire, portant avec elle son intérêt de chaque jour, et faisant fructifier les épargnes les plus humbles, aussi bien que les capitaux les plus considérables.

"Créer une telle institution, c'était donner à l'industrie et au crédit public le plus puissant encouragement, c'était mettre à leur disposition l'instrument le plus propre à leur fournir à bon marché les capitaux nécessaires à leur développement."

The simple statement of this rather enthusiastic language is, that the Crédit Mobilier is to employ its funds in taking shares in companies whose public objects are important; and that it is to obtain such funds by the issue of drafts and debentures, some of which may pass as currency. As will be evident from the remarks which we have cited from the address of Pereire, the promoters of the undertaking claim to have a public object, and distinctly undertake to confer a great benefit on the French nation, as well as to obtain a profit for themselves.

The opponents of the company, however, contest the truth of these professions. They say that its promoters do not really care about the completion of great national undertakings; that they are wholly uninterested about the actual construction of railways or canals; that it is only intended that the company should buy and sell shares for a profit; that the object of those who organized it is a selfish one; in a word, that the sole intention is to speculate in the share market.

Particular circumstances attaching to the politics of the moment have given to the controversy between the partisans of this company an unusual interest. The government of Louis Napoleon has been compelled to ally itself rather closely with wealth, and especially with newly-made commercial wealth. The single defence of the *coup d'état* was the necessity of preserving industry and credit from the attacks of multitudes, who, either from bad theories or bad motives, were anxious for a new distribution of property. The trading class, who live by their industry and their credit, were influenced by this argument, and leaned towards the new government. The classes connected with the former governments of France were naturally disinclined to it. The legitimist noblesse could not approve the revival of the Bonapartist dynasty; the literary and oratorical statesmen of the Orleanist monarchy could find no place for their characteristic abilities in a government which enforced a silence on parliamentary eloquence and on newspaper eloquence, which did not wish to be supported by abstract speculation, which only valued administrative ability. These are the natural results of human nature. It is, perhaps, equally so that the class of mercantile men who would most rally round a court, would not be the highest class. A close proximity to a gorgeous gaiety does not suit a sober and stable industry. The eager speculator who is in haste to be rich, in order that he may spend his riches, will seek the scenes of expenditure the moment he is thought to have riches. From causes such as these, the imperial government of France has been obliged to surround itself with a certain class of speculators rarely found in palaces, without a greater check from men of higher cultivation and more stable opulence. It has been contended that the Crédit Mobilier, which has been avowedly patronized by the imperial government, is in reality a speculation of these courtiers. "I do not know," said M. Berryer, in an action

brought by a M. Goupo against the company, "if, since 1828, M. Goupo has frequented the Bourse; but suppose he has, who is it that reproaches him with it? La Société de Crédit Mobilier; that is to say, the greatest gambling-house which the world has ever seen. We must not be misled by words. These are magnificent ones, I know: the protection of industry, the enfranchisement of the national credit, the development of private credit, the consolidation of all commercial stocks,—a dream. All that is the surface: they have given gambling a new name; they call it in their reports the industry of credit. The industry of credit! what is that? These twenty-eight millions of profit, how have they been produced? They are not due to the prosperity of the enterprises in which the Crédit Mobilier has taken a share, and to whose aid it has brought its great influence. No; they are the realizations which represent the difference between the price at which they sell, and the price at which they buy. It is gambling which has produced them. You are, then," he tells the company, "an institution of public utility; you have limited liability, and you play; you are irresponsible, and you gamble; you are a bank of play which sees the cards," &c., &c. In order to test the accuracy of these two conflicting views, we must refer to the statutes of the Crédit Mobilier which embody its design, and the accounts which record its history.

The preamble to its statutes states that its object is to "aid the progress of public works, and to consolidate into a common stock the shares and bonds of trading companies" (*de favoriser le développement de l'industrie des travaux publics et d'opérer par voie de consolidation en un fonds commun, la conversion des titres particuliers d'entreprises diverses*). The statutes specify that the company is to be one of limited liability, with shares of L.20 each (made out to bearer, and not the holders by name), and that its capital is to be L.2,400,000. The detail of its operations is to be as follows:—

"1. To subscribe or to acquire public funds or stocks; and also shares or bonds in various industrial enterprises, constituted on the principle of limited liability; particularly in railways, canals, mines, and other public works founded or to be founded.

"2. To issue, to the extent of a sum equal to the sum employed for purposes of the subscriptions and purchases aforesaid, the separate obligations of the society itself.

"3. To sell, or give as security for advances, all effects, shares, and obligations acquired or held by the society; and to exchange such effects, shares, and obligations against other values.

"4. To underwrite all loans, to undertake and realize them; also to undertake and realize all enterprises for public works.

"5. To lend on public securities, and on the deposit of shares and bonds, and to open credits, on account current, on the deposit of different kinds of value.

"6. To receive money on account current.

"7. To undertake all kinds of collections for companies, as aforesaid; to pay their interest and dividend warrants; and generally to undertake all business relating to such companies.

"8. To open a bank of deposit for all the securities issued by the companies aforesaid.—All other operations are interdicted.

"9. It is expressly understood that the society shall never undertake sales *à découvert* [that is, sales of stock, &c., merely for the account day or settlement], nor purchases *à primes* [that is, purchases which may be annulled by the payment of a mere fine or option].

"10. After the complete issue of the joint-stock capital of the society, the obligations created by the society may attain a sum equal to *ten times* the said joint-stock capital [that is, to (10 x 2,400,000) L.24,000,000].

Mobilier,
Crédit.

Mobilier,
Crédit.

"11. The accumulated amount of the sums received on account current, and the obligations of the society created, payable at *less* than one year's date or sight, shall not exceed twice the amount of the paid-up capital [that is, shall not exceed (2 × 2,400,000) L.4,800,000]."

(This translation of the statutes, which seems to us quite accurate, is taken from Tooke's *History of Prices*, vol. vi., p. 105.)

The government of the company is vested in a board of fifteen directors, elected by the shareholders, of which three go out annually, but are re-eligible. The board is bound to elect a president and two vice-presidents every year, who are likewise re-eligible, and to nominate a committee of management of five of its members, who are to regulate the detail of its affairs. The general meetings of the society are to be annual; but the directors have power to summon special meetings. At each general meeting an exact account of the financial state of the company is to be presented to the shareholders, and every six months such an account is to be laid before the minister of the interior, the head of the police, and several other public departments; and the minister of finance is to be at liberty to demand a statement in full detail of its intermediate operations whenever he pleases. No particular form of periodical accounts is prescribed; but by the seventh section of the statutes, which regulates the appropriation of the profit, 5 per cent. on the capital is to be first distributed to the shareholders by way of interest on such capital; 5 per cent. is then to be added to the reserve fund, and the remainder is to be divided between the directors and shareholders, in the proportion of $\frac{1}{10}$ th to the former and $\frac{9}{10}$ ths to the latter, —the directors being of course entitled to receive their quota as shareholders in addition to the $\frac{1}{10}$ th set apart for them by way of remuneration.

Of the annual accounts of the company, four have been published. The two first it will not be necessary to give in detail, but we shall most easily obtain a clear view of the nature of the company by the following comparison of the two last. The following were the liabilities of the establishment on the 31st December 1855, and 31st December 1856:—

	Dec. 31, 1855.	Dec. 31, 1856.
Capital	L.2,400,000	L.2,400,000
Deposits, current accounts	4,127,172	4,078,387
Bills payable, and sundries	34,576	13,046
Reserve fund	67,844	80,000
Total amount of profit in each year after carrying the proper sum to the reserve fund.....	1,073,116	601,235
	<u>L.7,702,708</u>	<u>L.7,172,668</u>

The assets of the company were,—

	Dec. 31, 1855.	Dec. 31, 1856.
Rents	L.1,602,770	L. 364,020
Debentures	1,313,784	2,123,231
Railway and other shares	2,377,364	1,195,343
	<u>L.5,293,918</u>	
Deduct for calls not made to 21st Dec. 1855	1,246,668	
	<u>L.4,047,250</u>	<u>L.3,682,594</u>
Investments for fixed periods in Treasury bonds, continuations and advances on shares, debentures, &c.....	3,373,016	2,031,201
Premises and furniture.....	43,288	53,456
Balance on hand, and dividends to be received on the 31st December last....	239,254	285,417
	<u>L.7,702,808</u>	<u>L.6,052,668</u> ¹

And its profit and loss account,—

	Dec. 31, 1855.	Dec. 31, 1856.
Profit on investments	L.1,042,675	L.457,463
Income from do., and interest on loans	232,155	231,193
	<u>L.1,274,830</u>	<u>L.688,656</u>
Less expenses	71,100	37,045
	<u>L.1,203,730</u>	<u>L.651,611</u>
Less depreciation of securities, &c.....	80,450	41,612
	<u>L.1,123,280</u>	<u>L.609,999</u>

Mobilier,
Crédit.

Note.—The difference between the expenses in the two years is principally owing to a sum of L.41,000 for interest on deposits, which, owing to a change in the mode of making up the account, does not appear in the second year. The depreciation of securities, &c., included in the first year some miscellaneous losses, to which there is nothing similar in the second year. The difference between the amount of profit here given, and that shown in the account of liabilities, has been carried to the reserve fund.

From these data we can at once determine the character of the bank. About half the funds at present at its disposal were, at the last date of which we have any information, invested in the purchase of shares, debentures, and similar securities of fluctuating value; and it is from augmentations in the value of such property that its profits are principally derived. Of the large profit of 1855, more than L.1,000,000 was so derived; and the remarkable diminution of entire income in the next year shows that the business of the company, like every other depending on purchase or sale, is very profitable in a rising market, and not by any means equally so in a falling market (like that of the latter months of 1856). The amount of profit so obtained would be deemed by English bankers very great. In 1855, 44 per cent. was realized on the capital; in 1856, 25 per cent., besides augmentations of the reserve fund in each year. Some of the large joint-stock banks in London have, it is true, on very rare occasions, made as much, or nearly as much, as 25 per cent. on their respective capitals; but then those capitals are, in proportion to their liabilities, comparatively small. The capital of the Crédit Mobilier is more than one-half its liabilities to the public; the capitals of the London and Westminster Bank, the London Joint-Stock Bank, and the Union Bank, vary from a fourteenth to an eighteenth of their respective liabilities. A comparison of the actual amounts of profit earned place the contrast in a more remarkable light. The London and Westminster Bank have made of 15 millions of money in the peculiarly profitable half year ending midsummer 1856, L.104,000, which is at the rate of L.208,000 per annum; the London Joint-Stock Bank, of 11 millions and a half, L.77,000 in the same half year, which is at the rate of L.154,000; the Union, of about the same amount of money, have made L.156,000. As will be seen by the above accounts, the income yielded by the Crédit Mobilier was in 1855 five times, and in 1856 three times as great as the highest of these, with only seven millions of money to employ profitably.

This amount of profit would generally appear to English bankers dangerously large, and their apprehensions would not be removed by the mode in which it is made. They would consider that it was dangerous to employ the money of other persons placed with them for brief periods in the purchase of the shares and bonds of miscellaneous companies, which are not readily saleable in times of difficulty, and are peculiarly fluctuating in price. The published documents and accounts of the Crédit Mobilier afford no satisfactory reply to these suspicions. They tell us

¹ The amount of assets in 1856 differs from that of the liabilities by L.120,000, because that sum (being 5 per cent. on the paid-up capital) was paid to the shareholders before the dividend meeting.

Mobilier,
Crédit.

more than once that the money which they hold cannot be hastily (*brusquement*) withdrawn from them; and likewise that in its origin the company only professed to receive the deposits of companies having the privilege of limited liability, with which it could probably make special agreements as to the time at which these deposits should be repaid; but the same documents also inform us that this intention has been departed from—that other money has been received, and they omit to inform us on what terms. It is much to be regretted that these authoritative expositions—which, like most of the reports of French financiers, are exceedingly elaborate, and, according to English notions, wordy—should leave the possibility of a doubt on a point so essential, and expose the company to the discrediting suspicion of employing in investments that cannot be immediately realized, money which may at once be withdrawn. We have obtained, however, from what we believe to be very reliable authority in Paris, the following particulars, which very much tend to diminish the importance which we should otherwise attach to this consideration:—We learn, first, that the Crédit Mobilier holds deposits, repayable either at call, or at five, ten, or thirty days' notice; and that the term of notice is determined by the amount of the deposit; the amount at call being limited in each case to sums not exceeding L.1000. Secondly, that though these are the terms of notice, yet in practice the company has not availed itself of its right to require such notice. Thirdly, that the deposits consist chiefly of monies belonging to railway companies, whose works are in progress, and that, as in every case at least one of the directors of these railway companies belongs to the council of the Crédit Mobilier, the latter has always in practice notice of the time when the money will be asked for. Fourthly, that the deposits, other than the monies of such railway companies, are only from L.50,000 to L.60,000. Fifthly, that a uniform rate of interest at $2\frac{1}{2}$ per cent. is given by the Crédit Mobilier for all such monies. If these details are, as we believe them to be, exact, the money held by the Crédit Mobilier is money over which they have a far greater control than other bankers have over the money which is left with them. The connection of the Crédit Mobilier with the companies who deposit such money is, in all likelihood, so close as practically to allay all apprehension of these deposits being demanded from feelings of apprehension; and the time at which they will be required for the works of the company to whom they belong must be known with great exactness. The Crédit Mobilier is in the position of a banker who receives large deposits from his personal friends; so long as they are his friends, he can be sure of their not being very hastily withdrawn from him. It is evident, however, that the scale of the operations of the Crédit Mobilier must be correspondingly restricted. There cannot be any very great amount of money in a position so peculiar as these deposits. As a general remark, no banker can have any very large number of personal friends that leave money with him; similarly, the amount of money in the hands of public companies very closely connected with the Crédit Mobilier must be of an amount strictly limited. Accordingly, as will be seen from the above accounts, the deposits did not increase during the year 1856, when the company was in the height of prosperity, its shares very high in price, and its dividend more than 40 per cent.; and we can hardly expect that they will increase hereafter, when circumstances are less favourable.

So far, therefore, as the employment of the funds left in deposit with the Crédit Mobilier is concerned, we have no reason to believe that it can accomplish the magnificent designs with which it was founded. The funds derived from that source are, and must continue, too small to revolutionize industry, or to consolidate in one common stock

the shares of different companies. The original design, as appears from the above citation from the statutes, was, that the Crédit Mobilier should derive additional funds by the issue of bonds, the smaller of which should pass as currency, and the larger be held by capitalists who were desirous of investing their money at a fixed rate of interest. Neither of these operations has as yet been found practicable. The imperial government has not permitted the issue of any such bonds, and the resources of the company have been therefore less than they were expected to be. We may, however, much question whether, even without the prohibition of the government, the scheme would have realized the expectations of its framers. The smaller drafts which were to be issued as currency would have been inferior in a material point to the notes of the Bank of France, which now constitute the French circulation of paper. The tendency of commercial improvement is to confine the function of credit-currency more and more to documents payable on demand. There used to be a very extensive circulation of bills in Lancashire, but it has yielded gradually to the superior convenience of the Bank of England note. *Ceteris paribus*, it is obvious that a note payable on demand is better adapted for circulation among many persons than one payable at a distant date. Each holder of the former feels that he can test its value whenever he pleases; holders of the latter cannot do so until the day on which it becomes due arrive. There are, we believe, legal difficulties in France, as well as in England, attaching to overdue negotiable instruments which render all notes and bills payable at a fixed time inapplicable as currency after that time. We cannot, therefore, anticipate that the drafts of the Crédit Mobilier will be able to compete as currency with the notes of the Bank of France, which have the additional advantage of being now in use. If, however, the Crédit Mobilier could succeed in maintaining its drafts in circulation, we should see no objection to its so doing. They would have the ordinary advantage of paper money; if they displaced other forms of circulating credit, we may assume that the public, in giving that preference, was not acting without some reason. If a portion of metallic money were displaced, the French nation would to that extent benefit by an economy of capital. While, therefore, we cannot expect, we do not dread that the Crédit Mobilier will circulate its drafts as a currency. A different objection applies to the bonds which were to be purchased as fixed investments by capitalists, like railway debentures, and the bonds of the Crédit Foncier. The first requisite of such bonds is a specific security. That of railway debentures is the revenue of a line of railway of which accounts are constantly published; and that of the Crédit Foncier is the landed property on which the funds of the society are advanced. The property on which the bondholder is to rely, is in both cases very evident to him. This is not so with the property of the Crédit Mobilier. We do not in the least know the contents of its *porte feuille*,—which shares it holds and which it has disposed of, and which it has never purchased. By the distinctive design of the Crédit Mobilier, the property belonging to it cannot be so stable in value, or so generally intelligible in character, as the property of the Crédit Foncier. No shares in bonds or moveable property of a country can ever be so fixed in price, or so well understood by the mass of men, as the acreage of the country in which they live. It is possible that a long course of good management and success may enable the Crédit Mobilier to raise some money on the security of shares and bonds whose names are not known to the public; but the progress of such an operation must be slow, and its range very limited.

We cannot therefore anticipate for the Crédit Mobilier the enormous and beneficial influence which its promoters announced and perhaps anticipated that it would have.

Mobilier,
Crédit.

Mocha. This also appears to be the opinion of the public. The shares, which, when L.10 only was paid on them, were worth L.70, are now, with L.20 paid, worth less than L.30; and their price has been for some months past (we write on the 20th of December 1857) steadily dropping. At the same time, however, we cannot expect from it the great evils which its extreme opponents have predicted. The limitation of its means tells on one side of the argument as well as on the other. It may seem, indeed, that the L.4,000,000 of deposits held by the company are a considerable sum for Bourse operations, and would be adequate to the requirements of a first-rate speculator. But the same circumstance which gives the company a peculiar control over these deposits, likewise controls the company, we have no doubt, in their employment. The railway companies who leave their money with the *Crédit Mobilier* expect the latter to take shares. The funds of the bank are doubtless largely invested in the undertakings carried on by its depositors; and it is only the amount not so invested which can remain applicable to common speculation. The denunciations of M. Berryer are therefore subject to important deductions, as well as the eulogium of M. Pereire. If we regard the company as a great railway bank, holding railway monies on peculiar terms, and investing much of its funds in the purchase of railway property, we obtain a view of its operations too distinct to warrant extreme apprehension or great hope. It is mainly from political considerations that a bank of such limited resources has obtained a European reputation.

(For further information as to the *Crédit Mobilier*, we may refer to two very able articles by M. Facade in the *Revue des Deux Mondes* for 15th May and 1st June 1856; and Tooke's *History of Prices*, vol. vi., pp. 104-130. For the ultimate data for these accounts of the company, as well as of our own, the reader may consult its published reports and accounts.) (W. B.—T.)

MOCHA, or **МОКНА**, a city and seaport of Arabia, in the province of Yemen, is situated on the Red Sea, about 40 miles N.N.W. of the Straits of Bab-el-Mandeb; Lat. 13. 20. N., Long. 43. 20. E. The town is built on the edge of a sandy plain, near the shore of a bay formed by two low promontories, on which are built forts for the protection of the harbour. The city, when viewed from the sea, presents a striking and beautiful appearance, as the houses along the shore, which are the best in the place, are high, well built, and white-washed; while in the background several mosques are conspicuous, one of which is of great size. On a nearer approach, however, Mocha is by no means so attractive; for its appearance is mean, and it is disfigured by ruinous buildings and dirty streets. The city is surrounded by walls, but the fortifications are not of great strength. The principal building is the residence of the *dola*, or governor. The bay is accessible to vessels drawing 10 or 12 feet of water, but those of a larger size are obliged to anchor in the roads outside the bay. The principal article of export is coffee, for which Mocha is famous. The plant does not grow in the immediate neighbourhood of the town, which is a barren desert, but among the forests and hills of the interior, whence the beans are conveyed and sold to the Mocha merchants. Before the beginning of the present century the great demand for coffee in Europe contributed greatly to the wealth and prosperity of Mocha. Since then, however, the cultivation of coffee in the West Indies, and its exportation from thence at a cheaper rate, have affected the coffee trade of this port. The quantity annually exported is estimated at more than 10,000 tons. The principal other exports of Mocha are,—dates, gum of various sorts, frankincense, myrrh, balm, gold-dust, ivory, sharks' fins, rhinoceros' horns and hides, aloes, &c.; and the principal imports are rice, iron, hardware, &c. The trade of Mocha is chiefly in the hands of Banian Indians. Pop. 7000.

MODEL, in a general sense, signifies an original pattern, proposed for any one to copy or imitate.

This word is particularly used, in building, to signify an artificial pattern in wood, stone, plaster, or other matter, of some intended structure, with all its parts and proportions; being intended to give an idea of the effect it will have in its proper dimensions, and to serve as a guide in its execution. In all great buildings, it is much the surest way to make a model in relief, and not to trust to a bare design or draught. Models are also used for the building of ships, and for many other purposes.

In academies for painting and sculpture, the term *model* is given to a naked figure disposed in any particular posture, to assist the artist while executing a figure in a similar attitude.

Models in imitation of any natural or artificial substance are most usually made by means of moulds composed of plaster of Paris. The particular manner of making models, or *casts*, as they are also called, depends on the form of the subject to be taken. The process is easy where the parts are elevated only in a slight degree, or where they form only a right or obtuse angle with the principal surface from which they project; but where the parts project in smaller angles, or form curves inclined towards the principal surface, the work becomes more difficult. Bodies that are soft, however, may often be freed from the mould, even although they possess the latter shape. When a model is to be taken, the surface of the original is first to be greased, in order to prevent the plaster from sticking to it; but if the substance itself be slippery, as is the case with the internal parts of the human body, this need not be done. When necessary, it may be covered over with linseed oil by means of a painter's brush. The original is then to be placed on a smooth table, previously greased or covered with a cloth, to prevent the plaster from sticking to it; then the original is surrounded with a frame or ridge of glaziers' putty, at such a distance from it as will admit the plaster to rest upon the table on all sides of the subject for about an inch, or as much as is sufficient to give the proper degree of strength to the mould. The liquid plaster is then to be poured as uniformly as possible over the whole substance, until it is everywhere covered to such a thickness as the requisite strength of the mould, increasing with the size, may require. The whole must then be suffered to remain in this condition until the plaster has attained its hardness. When the frame is taken away, the mould may be inverted, and the subject removed from it; and when the plaster is thoroughly dry, let it be well seasoned. The mould being thus formed and seasoned, it must next be prepared for the cast by greasing the inside of it with a mixture of olive oil and lard in equal parts. It may now be filled to the brim with fine fluid plaster, and the thickness further increased by the addition of coarse plaster, to form a strong basis or support for the cast where this support is requisite, as is particularly the case where the thin and membranous parts of the body are to be represented. After the plaster is poured into the mould, it must be suffered to stand until it has acquired the greatest degree of hardness it will receive, after which the mould must be removed; but this will be attended with some difficulty when the shape of the subject is unfavourable, and in some cases the mould must be separated by means of a small mallet and chisel. If by these instruments any parts of the model should be broken off, they may be cemented by making the two surfaces to be applied to each other quite wet, interposing betwixt them a little liquid plaster, and then smoothing the joint after being thoroughly dry. Any small holes which may be made in the mould can be filled up with liquid plaster, after the sides have been thoroughly wetted, and smoothed over with the edge of a knife. In many cases it is altogether impracticable to prepare a mould of one piece, for a whole

Model.

Modena. subject; and therefore it must be considered how this can be effected in such a manner as to divide the mould into the fewest pieces. This may be done by making every piece cover as much of the pattern as possible, without surrounding such projecting parts, or running into such hollows, as would not admit a separation of the mould. To make a mould upon a hard and dry substance, the surface must in the first place be rubbed smoothly over with the mixture of oil and lard above mentioned. Such hollows as require internal pieces are then to be filled up with fluid plaster, and whilst it continues in this state, a wire loop must be introduced into it, by which, when hardened, it can be pulled off.

After the mould is completely formed, it requires to be dried either naturally or by a gentle artificial heat, and then seasoned. This being done, nothing more is requisite to form the model than to pour into it the finest liquid plaster of Paris. After a layer of this, about half an inch in thickness, has been formed all round the mould, the coarser kind may be used to fill it up entirely, or to give to the model the thickness required. Besides the models which are taken from inanimate bodies, casts of the living face are frequently made, and this art has been brought to great perfection.

The method of making models in plaster of Paris is undoubtedly the easiest way of obtaining them. When models, however, are made of large objects, they must be constructed by the hand with some soft substance, as wax, clay, putty, &c.; and it being necessary to keep all the proportions mathematically exact, the construction of a single cast of this kind is a work of great labour and expense.

MODENA, DUCHY-OF, an independent sovereign state in the north of Italy, extending from the Po to the Mediterranean, from 43. 56. 45. to 44. 58. of N. Lat., and from 9. 15. to 10. 53. of E. Long. The portion lying on the sea is very small, and has no ports or harbours. It is bounded on the N. by Lombardy and the Papal States, on the E. by the Papal States and Tuscany, on the S. by Tuscany, Sardinia, and the Mediterranean, and on the W. by Sardinia and the duchy of Parma. Its greatest length, from Portovecchio, its northern frontier on the province of Mantua, to the outlet of the torrent Parmignola, on the Sardinian frontier, is 84½ miles; and its greatest width, from the pass of Calama, on the Tuscan and Papal frontier, to the right bank of the Enza, on the frontier of Parma, is 37 miles. It has an area of 2371 square miles, of which 598,120 acres are of flat, and 890,880 acres of mountainous country. In 1855 it contained 606,139 inhabitants.

The S.W. part of the duchy is traversed from N.W. to S.E. by the main ridge of the Apennines, of which the highest peaks are Monte Cimone, 7084 feet above the level of the sea; Monte Cruna, 6762 feet; Monte Succiso, 6630 feet; and Camporaghena, 6542 feet. It contains many small lakes among the mountains, and is watered by the Magra and the Serchio, which fall into the Mediterranean. The N.E. part, which forms a portion of the great basin of the Po, is a level plain sloping very gradually from the Apennines, and watered by numerous small streams, which finally unite in the Secchia and Panaro, and empty themselves into that river. This part is intersected by numerous canals formed chiefly for the purpose of irrigation.

The soil of the N.E. or flat part of the duchy is generally fertile, and the system of cultivation very much resembles that already fully described in this work under the head **LOMBARDY**, except that olive trees are more numerous here than in the north. The vine is extensively cultivated about Reggio and Modena, and produces a strong, rough wine, a large quantity of which is exported to Lombardy. The high district of Garfagnana is entirely devoted to dairy pasture. Olive trees, vines, and orchards form the cultivation of the small district on the sea-shore. Silk, of

which the greatest quantity is sent to foreign markets in a raw state; wheat, maize, hemp, and flax, are the other principal objects of culture; the two latter articles are coarsely manufactured for domestic consumption. Agriculture is chiefly carried on on the *métayer* system, and forms the principal pursuit of the larger portion of the population; for land being greatly subdivided, farms are generally very small. In the upland districts chestnuts form the principal food of the peasantry; while in the plain, *polenta*, or porridge made of Indian corn meal, is chiefly used.

In 1848 the acreage of the soil was distributed in the following manner:—734,810 acres were occupied by arable lands, meadows, &c.; 8996 by olive trees; 121,376 by chestnut trees; 3655 by vineyards; 121,815 by woods; 366,241 by buildings, roads, &c.; and 133,033 by waste land; giving a total of 1,489,926 acres. The value of the agricultural produce of 1854 was estimated at 88,611,986 Italian lire, or L.3,544,499, which, divided by the number of inhabitants in the same year, would give a produce of 146.19 lire, or L.5. 16s. a head.

The following are the detailed values of various articles of produce in 1854:—Wheat, L.823,855; Indian corn L.504,185; rice, L.66,774; other grain, L.116,701; chestnuts, L.185,450; oil, L.231,722; wine, L.1,031,694; cheese, wool, leather, &c., L.112,000; silk, fruit, &c., L.260,000. The number of live stock in the same year was,—cattle, 221,330; horses, mules, &c., 27,260; swine, 91,740; sheep, 341,200.

The *Stati Estensi*, as the duchy is officially styled in Italian, are divided into six provinces and seventy-two communities. The government is entirely in the hands of the Duke, who is assisted by several ministers and a council of state. The judicature consists of two supreme courts at Modena and Massa, and two inferior ones at Modena and Reggio. The code of laws is the same as that of Austria. Roman Catholicism is the established religion, and the hierarchy consists of an archbishop and four bishops. The educational institutions of Modena consist of a lyceum at the capital, and colleges for law and medicine at Modena, Mirandola, and Reggio; but the education of the people is at the lowest ebb. The military force consists of 3500 regular troops and three regiments of militia, amounting to a total of 14,656 men.

In 1855 the population was classified as follows:—

Provinces.	Communities.	Area in acres.	Inhabitants.
Modena	13	398,720	212,440
Reggio	14	472,960	166,696
Guastalla	6	81,920	52,220
Frignano	8	263,680	59,713
Garfagnano	17	140,160	38,705
Massa Carrara	14	160,200	76,385

Total72..... 1,517,640.....606,159

In this number there were 227,586 proprietors; 337,507 belonging to the agricultural class; 2648 following liberal professions; 109,500 day-labourers and servants; 40,075 tradesmen; 15,723 merchants; 11,577 shepherds; 3623 operatives; 3586 priests and monks; and 19,076 beggars. A custom-house union with Austria was stipulated in 1849; but the commerce of the state is not considerable. In 1855 the exports amounted to L.312,447; of which Carrara marble, L.48,000; cattle and swine, L.120,000; wine, brandy, vinegar, &c., L.5600; silk, cheese, skins, grain, &c., L.138,800. The imports, chiefly colonial commodities and articles of luxury, amounted to L.224,731. In 1851 the annual revenue of the state was L.336,545, and the expenditure L.349,125; leaving a deficit of L.12,380, which was made up partly by extraordinary taxes, and partly by the revenue derived from a large patrimonial estate of the Duke near Treviso, formerly in the possession of the Obizzi, a branch of the House of Este. There is no funded debt. In 1851 Modena was united with Austria by telegraphic

Modena.

Modena. lines; and on the 1st January 1852 the metrical decimal system was adopted instead of the ancient weights and measures of the country.

History. The sovereign of the state, who is an Austrian archduke, bears the title of His Royal Highness the Duke of Modena, Reggio, Mirandola, Guastalla, Massa, and Carrara. Through the female line he is descended from the House of Este, one of the most ancient families in Europe. Adalbert, a powerful marquis who lived towards the end of the ninth century, is the earliest ancestor to whom the learned Muratori was able upon documents to trace this family. Both Muratori and Leibnitz supposed him descended from the dukes and marquises of Tuscany; but as the latter lived *lege ripuaria*, and Adalbert, on the contrary, lived *lege Longobardica*, it is more likely that he descended from some great Longobard family. His grandson Oberto married a sister of a Marquis Ugo, who brought him as dower the castle of Este situated at the foot of the Euganean Hills, from which henceforth the family took their name. Alberto Azzo II., Oberto's grandson, married twice. By his first wife, Cunizza or Cunegunda, a sister of Guelph III., Count of Altdorf in Swabia, he had a son Guelph, who, at his uncle's death, without issue, in 1054, was acknowledged heir to that family's estates. He became Duke of Bavaria and founder of the House of Brunswick, and consequently of the present reigning family of Great Britain. Folco, another son of Alberto Azzo II. by his second wife Garisenda, a daughter of Herbert, Count of Maine, was the founder of the Italian branch, from which the dukes of Ferrara and Modena sprung. Alberto Azzo II. died, nearly one hundred years old, in 1097, and seven centuries afterwards, in 1776, William Henry, Duke of Gloucester, his direct descendant, erected to him a statue in the Prato della Valle at Padua.

Most of the present *Stati Estensi* formed in the eleventh century part of the vast possessions of Countess Matilda, the daughter of Bonifazio, Marquis of Tuscany. After her death in 1115, they came into the power of the Emperor Henry V., who descended into Italy and made himself master of her states. At his death in 1125 Modena acquired a certain independence, and soon afterwards engaged in constant warfare against its neighbour, Bologna. In 1249 the Modenese suffered a great defeat from the Bolognese at Fossalta, and their leader Enzo, son of the Emperor Frederic II., was made prisoner. After many years of civil faction, they invited Obizzo II. of Este, lord of Ferrara, who was proclaimed lord of Modena in 1289. At the beginning of the fourteenth century, however, Modena rid itself of its new master; but after thirty years of revolutions, in 1336, fell again into the power of Obizzo III. of Este; while, in 1409, Nicolo III. of Este having conquered Reggio, the district of Garfagnana surrendered to him without a contest. His son Borso in 1452 received the title of Duke of Modena and Reggio from the Emperor Frederic III., but continued to reside at Ferrara.

In the sixteenth century the Duke Alfonso I., the fourth husband of the famous Lucrezia Borgia, the daughter of Pope Alexander VI., having joined the League of Cambray against Venice, Pope Julius II., who deserted the League, took away from him Modena, Reggio, and Carpi. Modena was soon given up to the Emperor Maximilian, from whom, in 1514, it was bought back for 40,000 ducats by Leo X. Under Clement VII., however, in 1527, Alfonso I. having advanced upon the town, the inhabitants, tired of the papal sway, proclaimed him their master; whereupon the Emperor Charles V. declared that Modena, Reggio, and Carpi, belonged as imperial fiefs to Alfonso.

Under the reigns of Alfonso I. and of his two successors, Ercole II. and Alfonso II., letters and arts flourished at Ferrara, as well as at Modena and Reggio. It was Alfonso

I. who, in 1522, appointed Ludovico Ariosto, the greatest romantic poet of Italy, governor of Garfagnana, and Alfonso II. was the hero of Torquato Tasso.

At the death of Alfonso II., without male issue, in 1597, the eldest branch of the House of Este having become extinct, Alfonso, by his will, nominated his cousin Cesare d'Este as his successor. Cesare, who was a natural grandson of Alfonso I., was recognised as Duke of Modena, Reggio, and Carpi, by the Emperor Rudolph II.; but Pope Clement VIII. would not recognise him as Duke of Ferrara, and carried against him both temporal and spiritual arms. At length, by a treaty signed at Faenza on the 12th January 1598, Ferrara was taken from Cesare and incorporated in the States of the Church, while Modena from that time became the capital and ordinary residence of the House of Este.

Cesare died in 1628, and was succeeded by his son Alfonso III., who, after a year, having lost his wife, Isabella of Savoy, abdicated the throne in favour of his eldest son Francis, and became a Capuchin friar, under the name of Father John Baptist of Modena.

Francis I. patronized for a time the poets Tassoni, Graziani, and Testi, and began to build the ducal palace. His grandson Francis II. continued the palace, and founded the university and the library. At his death, without children, in 1694, the duchy came to his uncle, Cardinal Rinaldo d'Este, a son of Francis I., who gave up the cardinal's hat, and married Charlotte Felicia of Brunswick. Thus the two branches of the Este family, which had been separated since the eleventh century, were again united.

During the war of the Austrian succession, 1740-48, Modena and Reggio were occupied in turn by the French and imperial armies; but by the peace of Aix-la-Chapelle in 1748, they were restored to Rinaldo's son, Francis III., who died in 1780. His son and successor, Ercole Rinaldo III., who in 1741 had married Maria Theresa Cybo Malaspina, the last offspring of her family, and heiress of the duchies of Massa and Carrara, being driven out of Modena in 1796 by the French invasion, appointed a regency, and retired to Venice. His estates were then formed into a province of the Cisalpine republic, and by the treaty of Campoformio in 1797, he was to receive as indemnification a principality in the Breisgau. Ercole Rinaldo, however, would not accept the Swabian state, and died an exile at Treviso in 1803, leaving an only daughter, Maria Beatrice d'Este. Besides her claim to the paternal estates, Maria Beatrice was, in virtue of her mother, Duchess of Massa and Carrara; and in 1771 had been married to the Archduke Ferdinand of Austria, a son of the Empress Maria Theresa, and a brother of the Emperor Joseph II. and of Leopold II. of Tuscany.

In 1805 Modena and Reggio formed part of the kingdom of Italy, which replaced the Cisalpine republic. Massa and Carrara, by a decree of Napoleon of March 30, 1806, were united to Lucca, which had been erected into a duchy and given to Prince Felix I. and Eliza Baciocchi.

After the fall of Napoleon, by the treaty of Fontainebleau, April 10, 1814, ratified by the treaty of Vienna in 1815, the former states of the House of Este were given to Francis, eldest son of Ferdinand of Austria; Lunigiana, Massa, and Carrara, were restored to his mother, Maria Beatrice of Este, and at her death in November 1829 were inherited by Francis, and joined to the *Stati Estensi*.

The extinction of the male line of the House of Este was a misfortune to the duchy. The princes of that family, with all their faults, always had more or less patronized letters and arts; and as they had to rely on the support of their subjects, they could not act constantly in direct opposition to their wishes and interests. The new prince, who took the name of Francis IV., had no congeniality of feelings with his subjects, looked upon them as a conquered

Modena. race, and was nowise solicitous to gain their affections, as he knew that he could always rely for support on the whole strength of the Austrian empire.

The bad effects of the change appeared prominently in 1821, after the fall of the Sardinian and Neapolitan constitutions. Though in the duchy there had been no insurrection, yet many persons, on a suspicion of belonging to secret societies, were imprisoned, hastily tried, and sent to the galleys, and even to the scaffold. It was on that occasion that the present distinguished chief librarian of the British Museum, Mr Panizzi, was obliged to flee for safety from his country, where he was executed in effigy.

The French revolution of 1830 gave fresh encouragement to the liberal party throughout Italy. (See ITALY.) Francis IV., either from fear, or with the hope of enlarging his territory, promoted with arms and money the liberal movement, which first broke out at Modena on the 3d of February 1831. But a large Austrian army having advanced and put down the insurrection in Central Italy without any interference on the part of France, Francis returned to Modena; and to make amends for his coquetting with the liberals, distinguished himself by numerous and cruel state trials, which carried misery and dismay into every family. Among the first victims sent to the scaffold was Ciro Menotti, a young man who had been on the most friendly terms with the Duke, and had led the Modenese movement at his instigation. The remaining years of Francis's life were equally marked by reaction and political prosecutions. It was under his protection that a Jesuitical journal, *La Voce della Verità*, was started at Modena, which became so violent in its attacks upon England, that at length Lord Holland, then the British plenipotentiary in Tuscany and the duchies, was obliged to interfere.

Francis IV. died in 1846, and was succeeded by his son, Francis Ferdinand V., the present Duke, who at first adopted a less oppressive course of government. In October 1847 he added to his estates the districts of Galliciano, Montignoso, and Fivizzano, which were given up by Tuscany on receiving the duchy of Lucca, according to a treaty of November 1844; and in January 1848 he also added the small duchy of Guastalla, and a district on the right bank of the Enza, which were received in exchange for the smaller districts of Villafranca, Castevoli, Treschietto, and Mulazzo, from Carlo Ludovico Borbone, who, having surrendered Lucca to Tuscany at the death of the Empress Maria Lousia in December 1847, had become Duke of Parma.

The liberal agitation of 1847 drove Francis Ferdinand V. into a course of stringent measures and persecutions. He had an Austrian detachment to garrison Brescello, and by an offensive and defensive treaty of February 1848, both he and the Duke of Parma empowered Austria to occupy their estates in times of danger. After the insurrection of Lombardy, the Austrians having found it necessary to withdraw, Francis took refuge in the fortress of Mantua, and the *Stati Estensi* by universal suffrage joined Sardinia. On the defeat of the Sardinian army in August 1848, Francis returned to Modena, which, however, on the resumption of hostilities, he again left and retired to the fortress of Brescello. He returned to his capital in May 1849, after the final defeat of Charles Albert, and ever since has followed a comparatively mild and more conciliatory policy.

MODENA (ancient *Mutina*), the capital of the above duchy, is situated in 44. 38. 52. N. Lat., and 10. 26. 5. E. Long., between the Rivers Secchia and Panaro, on the banks of a canal which connects it with both these rivers. In ancient times Mutina was an important town of Gallia Cispadana, situated on the Via Æmilia. It was probably founded by the Etruscans, and afterwards fell into the hands of the Romans in 218 B.C., who, thirty-five years later, established a colony here, after annexing the country

belonging to the Boians, in which it was situated. Civic rights were soon accorded to the inhabitants, and the great Via Æmilia constructed in order to develop the resources of the district. In 117 B.C., however, the settlers were disturbed by an incursion of the Ligurians, who for a short time held possession of the town. They were ultimately expelled by Consul Claudius, who inflicted a severe chastisement on the intruders. The next mention we have of Mutina is during the civil war, when in 78 B.C. it was held by M. Brutus against the victorious Pompey. Its most memorable occurrence in history, however, was during the *bellum Mutinense*, in 43 B.C., when it sustained a siege of about four months against the troops of Mark Antony. After the rupture of the latter with Octavius, he established a close blockade of Mutina, then garrisoned by Decimus Brutus. The forces of Antony held Bononia as well as Parma and Regium; while the main army, under his own leadership, kept up the siege of Mutina. For the relief of the latter the Senate had sent Consuls Hirtius and Pansa, besides the young Octavian. As Pansa was marching up to the support of his colleague with some newly-raised legions, he was attacked by Antony on the Bononian road, about eight miles from the besieged town. A severe action ensued, when the consul was mortally wounded; but Hirtius, taking the opportunity to attack the rear of Antony's army, forced him to retire to his camp before Mutina. The successful consul, however, was slain some days after, in a second battle near the town, which, nevertheless, had the effect of obliging his antagonist to raise the siege. In later years the town was besieged and taken by Constantine in 312 A.D., during his war with Maxentius; while after the decline of the empire it suffered severely from the barbaric invasions, and in 452 was laid waste by Attila. After the Longobard conquest it became the frontier city of their kingdom towards Ravenna; yet it gradually fell into such a state of decay, that in the tenth century it was almost totally deserted, and its site had in part become a morass. Most of the ancient buildings were allowed to go to decay, and ultimately became buried in the soil. From this abject state Mutina began to recover in the eleventh century, under the government of Countess Matilda, and gradually rose again to such prosperity, that in the fourteenth century it was already a very flourishing and opulent city.

The modern town is surrounded with walls, and defended by bastions and a citadel, which, though much enlarged and strengthened by the late Duke Francis IV. since 1830, is not capable of much defence. The city is well built, with a broad street running between two opposite gates. The houses are handsome, and many of them furnished with piazzas, or covered porticos, on the ground-floor. The ducal palace, which was begun by Francis I. in the seventeenth century, from the designs of Avanzini, and finished by the present Duke, Francis Ferdinand V., is a fine marble building, with several courts, open staircases, galleries, &c.; and still contains a large collection of paintings, though the best of them were sold in the last century, and form now the chief gems of the Dresden Gallery. In a wing of the palace is a collection of more than 25,000 coins and medals, and a museum of ancient sarcophagi, inscriptions, and curious mediæval sculptures. In the same wing is also the *Biblioteca Estense*, or library, of 90,000 volumes and 3000 MSS., founded at the end of the seventeenth century by Francis II. Muratori, Zacharia, and Tiraboschi, three of the most learned men of Italy in the last century, were successively its librarians. The *Duomo*, or cathedral, begun by the Countess Matilda in 1099, is a very fine building, in what is called the Lombard style of architecture. Its bell-tower, or *Ghirlandina*, as it is named, from the bronze garland which surrounds the weathercock, is lined with marble, and attains a height of 315 feet. The worm-eaten *Secchia*, or wooden bucket, which, taken by the Modenese

Modena.

Modern
||
Möen.

from the Bolognese at the affray of Rapolino, November 15, 1325, formed the subject of Tassoni's well-known poem, *La Secchia Rapita*, was at the time solemnly deposited, and is still kept in the basement of this tower. There are within the city more than fifty churches, of which twenty-six formerly belonged to religious orders. The new theatre, the opera-house, and the barracks are the other most remarkable edifices. The university, which once was flourishing, has been closed for several years; and public education is now chiefly in the hands of the Jesuits, who are perhaps more flourishing at Modena than in any other Italian city. There is a Royal Academy of Arts, Sciences, and Letters, a Scientific Society, a Veterinary College, and college for the nobles; but there is little trade of any kind, and the inhabitants chiefly depend on agriculture and on the expenditure of the court for their subsistence.

Cardinal Sadoletto, the secretary of Leo X., Ludovico Castelvetro, the historian Sigonio, the poets Molza and Tassoni, and many other literary men, were born at Modena. Pop. (1855) 32,000. (***)

MODERN, MODRA, or MADRA, a town of Hungary, county of Presburg, is situated at the foot of the Carpathian Mountains, 16 miles N.N.E. of Presburg. The town is well built and walled, with three gates, adjoining each of which is a suburb. It has a Benedictine monastery and church; Roman Catholic, Lutheran, Calvinistic, and Bohemian churches; and a governor's house and town-house. There are woollen manufactories; and some trade is carried on here. Pop. 6000.

MODICA, anciently *Motyca*, a town of Sicily, capital of a district of the same name, in the province of Syracuse, on the Scieli, 31 miles W.S.W. of Syracuse. The town, which stands amongst steep and rugged hills, is generally ill built, though it has a large square and some fine buildings. The principal edifices are the palace of the Dukes of Berwick-Alba, a castle, several churches, convents, schools, hospitals, and a town-hall. Cotton-spinning and the rearing of cattle are carried on; and there is a considerable trade, especially with Malta. Not far from the town is the valley of Ipsica, which is remarkable for numerous caves hollowed out of the rocks. Pop. 22,000.

MODULATION, in *Music*, is a word which in our language is susceptible of several distinct significations. It frequently means no more than an air, or a number of musical sounds properly connected and arranged. Thus it answers to what is sometimes understood by the word *tune*, and likewise expresses the French word *chant*. But the precise and technical acceptance to which it ought to be confined, is the art of composing melody or harmony agreeably to the laws prescribed by any particular key, rather than of changing the key, or of regularly and legitimately passing from one key to another. (See *MUSIC*, sec. *Modulation*.)

MODUM, a village and parish of Norway, in the province of Aggershuus, is situated on the Drammen, 25 miles W. of Christiania. In the neighbourhood there are extensive cobalt mines, and manufactories of smalt. Pop. 4500.

MÖEN, an island of Denmark, in the Baltic, S.E. of Zealand, Lat. (of lighthouse on S.E. point) 54. 57. N., Long. 12. 37. E. It has a length of 18 miles, an extreme breadth of 13, and an area of 87 square miles. It is separated from Zealand by the Ulf Sound, and from Falster on the S. by the Gröen Sound. The scenery of this island is highly picturesque and beautiful. From the one end to the other, along the E. coast, there extends a range of hills, many of the summits of which are richly wooded, whilst others are quite bare. The highest altitude to which these hills rise is only 460 feet, and the rest of the island is low, flat, and fertile. There are numerous glens and ravines, through which brooks and torrents flow in all directions from the hills. Möen has no rivers of any size,

but there are a few small yet deep lakes. The chief town is Steege, on the N.W. coast, which has a good harbour. Pop. of island, 13,200.

MÆRIS. See EGYPT.

MÆSIA, a Roman province in Europe, was bounded on the N. by the Danubius (*Danube*), on the E. by the Euxine, on the S. by Mount Hæmus, and on the W. by the Drinus (*Drin*) and the Savus (*Save*). According to Strabo, it was originally peopled by emigrants from Thrace. It was first invaded by the Romans in 75 B.C.; but not until the reign of Augustus was it finally subdued, and reduced to the form of a Roman province. A line of fortresses was then planted for its defence along the southern bank of the Danube. The principal of these were afterwards known as Singidunum (*Belgrade*), Viminacium, and Axiopolis. In the interior were the towns of Marcianopolis, Sardica, and Naissus (*Nissa*). About the time of Trajan's reign, Mæsia was divided into two provinces—Mæsia Superior on the E., and Mæsia Inferior on the W., of the River Ciabrus (*Zebra*). In the reign of Decius the Goths secured a footing in the province, and were only induced to retire by a bribe from the succeeding emperor, Trebonianus Gallus. Numbers of them, however, afterwards returned, and settled down permanently. Their descendants were the Mæso-Goths, for whom Ulphilas translated the Scriptures about the middle of the fourth century. In the seventh century invading hordes of Bulgarians and Slavonians founded the kingdoms of Bulgaria and Servia, which now comprise the territory of the ancient Mæsia.

MOFFAT, a market-town of Scotland, in Dumfriesshire, is situated near the Annan, 19 miles N.N.E. of Dumfries. It is much resorted to as a watering-place on account of its mineral springs, of which there are three in the vicinity; viz., Moffat Well, $1\frac{1}{2}$ mile from the town; Hartfell Spa, at the distance of 5, and Girpell, of 2 miles. The first, however, discovered in 1633, is the only one frequented by visitors. Its water has a disagreeable taste and a strong sulphureous smell. The town contains Established, Free, and United Presbyterian churches; baths, assembly-rooms, a market-house, reading-room, and library. The market-day is Friday, and fairs are held three times a year. Pop. (1851) 1413.

MOGADOR, MOGODOR, or SUIRAH, a seaport-town of Morocco, situated on the Atlantic, 125 miles W.S.W. of Morocco, Lat. 31. 50. N., Long. 9. 20. W. It is built on a rocky eminence, surrounded by low sandy ground which at high-water is overflowed by the sea, leaving the town in an insulated position. The town, which is of an irregular form, consists of two parts, one of which, called the Citadel, is inhabited by Moors, while the other is occupied by Jews. Mogador is walled and fortified; but its defences, which are the work of Genoese engineers, are of no great strength. The streets are straight but narrow; and the houses are large and flat-roofed, but present a somewhat gloomy appearance. The principal buildings are the mosques, some of which are very handsome, the palace of the pasha, custom-house, arsenal, &c. The harbour of Mogador is formed by an island of the same name, which lies about a third of a mile to the S. of the town; and although it is much exposed, it is considered the best harbour on the coast. It might, however, be much improved. The city is supplied with water by an aqueduct, built by the present emperor, which conveys water from a river at the distance of a mile and a half to several tanks in different parts of the town. The trade of Mogador is considerable, and is chiefly in the hands of the Jews. The principal articles of export are wool, gum, wax, hides, skins, almonds, honey, ostrich feathers, ivory, gold-dust, &c.; the imports are iron, hardware, glass, woollens, linens, cottons, sugar, pepper, &c. The value of the exports in 1855 was L.284,078, and that of the imports L.167,718. Mogador

Cruzes.

was founded by the Emperor Leedy Mahomet in 1760, as the commercial capital of his empire. It was bombarded in 1844 by a French fleet under the Prince de Joinville, on which occasion it suffered severely. Pop. estimated at 16,000, of whom 4000 are Jews.

MOGHILEV, or MOHILEV, a government of Russia in Europe, bounded on the N. by that of Vitepsk, E. and S. by those of Smolensk and Tchernigov, and W. by that of Minsk. It lies between 53. 5. and 55. 10. N. Lat., and between 28. 50. and 32. 40. E. Long., having a length of 210 miles, a breadth of 112, and an area of 18,724 square miles. The northern part of the government is traversed by a low range of hills, which separate the streams flowing north from those which take a southern direction; but the greater part of the surface is flat, and there are few lakes or marshes. The principal river in the government is the Dnieper, which enters Moghilev from the N.E., and after flowing through the centre of the district, forms its boundary on the S.W. Of the tributaries of the Dnieper in this district, the most important are the Swinaja, the Bolotinka, and the Sodscha, on the left; and the Druetz on the right. The climate is mild and dry; and the soil, which is fertile, is equally suitable for cultivation and for pasture. A great part of the surface is covered with oak and pine woods, which furnish excellent timber for ship-building, especially for masts. Along the banks of the rivers there are extensive and rich meadows, on which large flocks and herds are fed. Iron ore is found in great abundance, but it is only worked to a limited extent, the inhabitants being employed principally in pastoral and agricultural pursuits. The quantity of corn raised annually amounts to nearly 23,080,000 bushels. Rye, barley, oats, wheat, buckwheat, hemp, flax, and hops, are the principal crops grown; and the quantity of these so exceeds the demand as to leave a considerable amount for exportation. The horses and cattle are of an inferior breed; but the sheep have been much improved by crossing with those of Saxony. The manufactures are insignificant, and are chiefly in the hands of Jews. A considerable trade is carried on in grain, hemp, flax, leather, honey, wax, &c. The government is divided into twelve districts; and the principal towns are Moghilev the capital, and Mstislavl. The inhabitants are chiefly Russniaks, or Little Russians, and there are also many Jews and gypsies. The language spoken in Moghilev is a mixture of Polish and Russian. Pop. (1846) 931,300.

MOGHILEV, or *Mohilev*, capital of the above government, is situated on the E. bank of the Dnieper, 85 miles S.W. of Smolensk, and 110 E. by S. of Minsk. The town consists of four quarters, one of which, the Kremlin or citadel, is built on a hill. Two other quarters form the main body of the city, and are surrounded by ramparts; and the fourth quarter consists of a suburb. The houses are well built, partly of wood and partly of stone. Many of the streets are broad and well paved; and in the centre there is a large open space of an octagonal shape, surrounded by handsome stone buildings, one of which is the archbishop's palace. The town contains twenty churches, of which the greater number are Greek, but five are Roman Catholic and one Lutheran. Moghilev has also four convents, two theological colleges, two schools, and several benevolent institutions. The chief manufactures of the town are those of ironware, leather, and tobacco; and a considerable trade is carried on with Riga, Königsberg, Dantzic, and Odessa, in hemp, glass, leather, hides, corn, oil, wax, honey, &c. Raw salt is imported. The town is ancient, but the date of its foundation is not known. It is the seat of a Greek archbishop and of the Roman Catholic primate of Russia and Poland. Many of the nobility reside here. Pop. (1851) 16,558.

MOGI-DAS-CRUZES, a town of Brazil, province of São Paulo, about 4 miles from the Tiete and 40 E.N.E.

from São Paulo. The town is chiefly built of mud, and contains four churches, a convent, and two schools. It has manufactures of woollen cloth, and a considerable trade in coffee, rum, sugar, and cotton. Pop. (of the district) about 9000.

Mogoo

Aleec.

MOGOO, a seaport of Laristan in Persia, which has one of the most secure roadsteads in the Persian Gulf. It is formed by Cape Bostana to the eastward, and by Point Certes to the west. It is capable of containing the largest fleets, and the entrances are about 10 miles asunder. It is 80 miles south of Lar.

MOGRIDGE, GEORGE, better known as "Old Humphrey," a popular magazine writer, was the son of a canal agent, and was born in February 1787 at Ashted, a suburb of Birmingham. He was educated at a boarding-school at Boarcote, near Bromsgrove, where he imbibed that love for the sights and sounds of the country which became so strong a feature in his character. After serving as an apprentice for several years, he was taken in 1811 into partnership with his elder brother, a wholesale dealer in japanware in Birmingham. Meanwhile his leisure hours had been enthusiastically spent in reading the poets, in contributing small articles in prose or verse to local newspapers, and in rambling through the most pleasant spots of English scenery. Not many years afterwards his brother's death left him to conduct the business alone. His total incapacity for mercantile affairs soon brought him to bankruptcy, and reduced his family to destitution. He now resolved to trust to literature for a livelihood, and settled down in an obscure and solitary lodging on the Kingsland road near London. There, harassed by extreme poverty, yet comforted by a deep and cheerful piety, he continued for several years to ply his facile pen unceasingly, and to produce volume after volume of simple life-like sketches and genial home-truths. At length, in January 1833, *Old Humphrey's Observations* began to appear in the Tract Society's magazine, the *Weekly Visitor*. The fond fidelity with which they transcribed the familiar sights and objects of the street and the rural by-path was the principal secret of their fame. But this charm was greatly heightened by their simple, garrulous style, their child-like humour, their practical wisdom, and their tone of human sympathy and of genuine and genial piety. In a short time "Old Humphrey" had attained the position of a moral teacher in the bosom of many a family throughout the land. His papers continued to be issued periodically for several years, until a selection of them was large enough to fill six volumes. These were published under the distinctive titles of *Old Humphrey's Addresses, Observations, Friendly Appeals, Half-Hours, Thoughts for the Thoughtful, and Pithy Papers*. Mogridge continued to write to the last, and died at Hastings in 1854, leaving his family nothing but his Christian example and the honour of his works. His life was published by the Rev. Charles Williams, London, 1856.

MOGULS. See ASIA and HINDUSTAN.

MOHACS, a town of Hungary, county of Baranya, on the western arm of the Danube, 25 miles E.S.E. of Fünfkirchen. It contains a castle; Roman Catholic, Greek, and Protestant churches; a handsome episcopal palace; a monastery; school; and county buildings. The commerce is considerable, and it has a quay on the Danube, whence wine, corn, wood, coal, &c., are despatched to Vienna. The steamers on the Danube also call here. Five fairs are held annually at Mohacs, and are very much frequented. In the neighbourhood of the town two famous battles were fought: the first in 1526, when the Turks, under Solyman the Magnificent, defeated the Hungarians with great loss; and the other in 1687, when the Turks in their turn were defeated by the imperialists under the Duke of Lorraine. Pop. 10,050.

MOHAMMAD-ALEE. See EGYPT.

Moham-
medanism.

MOHAMMEDANISM. An account of a religion which has exercised, and still exercises, so great an influence over a large portion of the human race, appears to demand the consideration of the following topics:—1. The history and character of its founder. 2. The probable causes of his success. 3. The Koran. 4. Other elements and characteristics of Mohammedanism. 5. Its social and political features. 6. Its principal sects. 7. Its literature, science, and art. 8. Its relation to heathenism. 9. Its relation to Christianity. 10. Its present condition and probable future.

Reference to various sources of fuller information under these different heads will, it may be hoped, enable the reader to fill up the outline here presented of the origin, progress, and character of Mohammedanism.

1. *History and Character of Mohammed.*—Mohammed, son of Abdallah and Amina, and grandson of Abdelmottalib, was born at Mecca in August 570 A.D. Gibbon inclines to a year earlier, but high authorities are against him. He was of the noble family of Hashem, of the tribe of the Koreish, confessedly the first and most honourable in Arabia. As his father Abdallah died shortly before the birth, the grandfather Abdelmottalib rejoiced greatly over the event, and at a feast held seven days after bestowed on his infant heir the name of Mohammed, or *The Glorified*. Later traditions told how, when the infant was born, the palace of the King of Persia was shaken by an earthquake, and the sacred fire of the Magi extinguished. Mohammed was nursed by a woman named Halima, and then by a black slave called Oumm-Ayman. Towards both, and especially towards the latter, he always displayed much gratitude and attachment.

At the age of six he lost his mother Amina. She was unable to leave him any property beyond five camels and the slave Oumm-Ayman. His grandfather Abdelmottalib (in some English works, Abdol-Motaleb) took him under his protection for three years, when he also died; and the lad, now nine years old, passed (A.D. 579) into the hands of his paternal uncles, one of whom, Abu Taleb, acted as his friend and guardian. Mohammed is believed to have been present at two battles fought between the tribe of the Hawâzin and the Koreish in 585 and 586, in both of which the Koreish were defeated, though they subsequently regained the advantage. About this time Abu Taleb took his nephew in his company on a mercantile expedition into Syria. The youth had attained his thirteenth year, and is said to have begun to attract attention, and give promise of future eminence. As in the case of many other famous men, however, it is difficult to decide how far such traditions result from the reflected glory of after life. Although endowed with a native penetration such as Thucydides in a famous passage ascribes to Themistocles, Mohammed was deficient in the elements of education: it is doubtful whether he could even read and write. So ignorant was he of the Arab rules of versification, that he seldom quoted a verse without some misarrangement of its words. In apparent allusion to these circumstances, we find him in one of the most celebrated chapters of the Koran declaring, "We have not taught Mohammed the art of poetry, nor is it expedient for him to be a poet" (chap. xxxvi.); as in a previous chapter, the seventh, he entitles himself "the illiterate prophet." There appears, however, no reason to doubt that by the age of twenty-five he had acquired a most honourable reputation among his fellow-countrymen. His readiness, his nobleness of conduct according to the Arabian standard, his good faith and aversion to anything dishonourable, won for him at this period the surname of *El-Amin*, the trustworthy.

An important epoch in his life now arrived. His reputation for honesty and ability induced a wealthy and high-born widow, named Kadajah, to employ him as her mercantile agent. His great success led to the offer on Kadajah's part

of her hand. Although between thirty and forty years of age, she had still several suitors. This match placed Mohammed in a position conformable to his origin. The change did not, however, unduly elate him. He showed delicacy in the employment of her property; and during her lifetime had no other wife. Of the six children of this union two sons died in infancy; the daughters lived to embrace their father's creed, and were married to disciples. One only, however, Fatima, outlived him, and became by her marriage with the famous Ali the ancestress of an illustrious family. The burst of feeling attributed to Mohammed, years after Kadajah's death, is well known. When a later wife, Ayesha, was claiming superiority on the score of youth, he is reported to have said, "There never can be a better! She believed in me when men despised me; she relieved my wants when I was poor and persecuted by the world."

Mohammed was twenty-five years old when he espoused Kadajah. We pass over his arbitration of a contest between rival branches of the Koreish, as to the honour of moving the famous black stone in the national temple at Mecca (the Kaaba), which this tribe, as its guardians, were (A.D. 605) reconstructing. His office on this occasion, however honourable, appears to have been accidental. But in the following year Mohammed, now thirty-six years of age, had the satisfaction of being able in some degree to repay the kindness of his uncle Abu Taleb, by taking charge of a young cousin Ali, already alluded to as one of the most zealous and famous of his future disciples. He likewise tried to console himself for the loss of his sons by Kadajah, by the adoption into his family of a young man named Zayd, son of Hâritha.

Mohammed's want of anything like regular education has been noticed. He appears, however, to have gained much information while on his travels as a merchant, and probably still more from intercourse with his wife's cousin Waraca, son of Naufal, the most learned Arab of his day. We incline to agree with Hallam, Taylor, Döllinger, and others, who think that Mohammed had no real acquaintance with the New Testament; but he gained a knowledge, though a vague and imperfect one, of the principal Jewish and Christian dogmas, of the Scripture history, of the contents of some of the apocryphal gospels, and of the Talmud. He was naturally well versed in the traditions and legends of his own country; and added to a resolute will and considerable strength of imagination a wonderful power of expression. His love of solitude was very great. He would wander, it is said, in the gorges and valleys around Mecca, and every year retired during the month of Ramadan to a neighbouring hill, Mount Hirâ. There he spent his time in prayer, and fed any poor who asked of him an alms.

We now come to the date (A.D. 611) when Mohammed, being in his forty-first year, asserts that he received his mission. About this time Britain is witnessing the foundation of a Christian church in London, now known as Westminster Abbey; Boniface IV. is pope at Rome; and the Anglo-Saxons, Jutes, and many more tribes in northern Germany, are adopting the faith of Christianity. The Greek empire is being ravaged by Persians and Avars; but Heraclius is preparing for resistance, and in the very year of the Hegira (A.D. 622) will start upon his glorious and successful expedition against Persia, and gain a signal victory for the cross.

The first passage said to be revealed is that which now stands as the commencement of the 96th *sura* (or chapter) of the Koran. "Read, in the name of thy Lord who hath created all things; who hath created man of congealed blood. Read, by thy most beneficent Lord; who hath taught the use of the pen; who teacheth man that which he knoweth not." He told Kadajah that the angel Gabriel had taught

Moham-
medanism.

Moham-
medanism.

him these words, and she at once accepted him as the prophet of the nation. Her cousin Waraca, now aged, and who died shortly afterwards, received the information in such a way as to confirm Kadijah in her belief. Ali, then eleven years of age, was the second convert. The new religion was termed by Mohammed *Iman* (belief), and *Islam* (resignation to the will of God); whence the adjective Moslem believer, and the corrupt form Mussulman. He shortly after made a new and valuable proselyte in Abu-Beker, a man of high consideration and remarkable for the beauty of his person. But a check followed; at a reunion of his cousins the announcement of his mission was received with coldness and incredulity; and when, not satisfied with teaching the unity of the Godhead and his own apostleship, he declared his intention of overthrowing idolatry and bringing his countrymen back to the religion of Abraham, indignation burst forth on all sides. It was proposed to silence him; and none were more vehement in their opposition than the other families of his own tribe, the Koreish. Abu-Taleb, though not a convert, continued to protect his nephew.

For the next few years Mohammed's life was passed in a state of persecution and insult which extended itself to his few disciples. Once, indeed, his adversaries made offers of wealth or leadership if he would cease from his endeavours; but he replied by the recitation of that chapter of the Koran which now stands as the 41st; a really sublime effusion, in which he reminds his hearers of the destruction of the city and tribe of Ad for idolatry; a legend known to English readers by the first book of Southey's *Thalaba*. The reply to this appeal was the very natural request that Mohammed would work miracles as a proof of his divine mission. This embarrassing demand is more than once alluded to in the Koran. His answer was, that he was sent to preach truth, not to work miracles; and that his opponents would not be convinced even if miracles were vouchsafed. Nevertheless, as if conscious of his weakness on this side, he in time proclaimed his famous night journey to heaven, known as *Isra*, when the angel Gabriel took him on the animal Borac to enjoy an interview with patriarchs, prophets, and the Almighty himself. This brought on him a storm of ridicule, and some of his disciples abjured his teaching. Abu-Beker stopped others from departure by professing his own entire belief in Mohammed's narrative.

In the eleventh year of his mission (A.D. 621) some new converts took oaths of fidelity, known as the oaths of Acaba, the hill on which they were taken. But fresh plots among the Koreish alarmed him; and in A.D. 622 he took the step of flying from Mecca to Medina, then known as Yathrib. This flight, known as the *Hidjra*, and in Europe as the *Hegira*, was, 17 years later, fixed as the great Moslem epoch by the Caliph Omar. Here he took up arms against the Koreish, and within two years (on the 18th of January 624) won the famous victory of Bedr. In the Koran (chap. iii.), he maintains that angelic aid was granted in this battle. Mohammed behaved generously to his prisoners, but made some of them teach his converts how to read and write. In the same year he was defeated at Ohod; but as this battle was lost by disobedience to his orders, Mohammed's reputation did not suffer. He resolved henceforth to give no quarter to the idolaters. About this time he had dealings with the Jews. A few accepted him as a prophet; but his claim of descent from Ishmael, and his partial admission of the claims of Jesus, repelled the majority. They became bitter enemies, and Mohammed caused at least one of their leading men, Khalid, to be assassinated.

In the meantime Mohammed had largely increased the number of his wives: he had in all fifteen, besides Kadijah. It was probably in the year 626 that he married Zeynab, daughter of Djahch. This was contrary to Arab usage,

for she was the wife of his adopted son Zayd; and no willingness on the part of the husband, who at once divorced Zeynab, nor on the lady's own part, could annul this difficulty. But a resource was at hand. In the 33d chapter of the Koran was given a permission to the Moslem to marry the wives of their adopted sons, these sons being in future called by the names of their actual fathers.

In A.D. 628, the 6th year of the *Hegira*, he began to send letters to sovereign princes, not only in Arabia, but beyond its limits. They were sealed with a silver signet containing in three lines the words, MOHAMMED—APOSTLE—OF GOD. Persia, Abyssinia, and Egypt were the first recipients. This is a new and marked feature in the history of Islamism.

In the following year he made some of his most distinguished converts,—Othman, Amr, and Khaled; but essaying his power against the Eastern Roman empire, his troops were defeated by Theodore, lieutenant of Heraclius. He was not present at this battle. Soon after, he gave great offence to his wives by continuing to cohabit with a Coptic slave, Maria, whom he had freed on the birth of a son. A fresh chapter (the 66th) of the Koran righted this matter also, but not without difficulty.

Eight years after his flight he was strong enough to gain possession of Mecca (January A.D. 630). Mounted on his camel, he rode seven times round the Kaaba, then having on its roof 360 idols. He had every one of these destroyed before his face, saying the while, "*The truth is come; let falsehood disappear*" (Koran, chap. xvii.) That day was perhaps the grandest of Mohammed's life.

But by this time he had fully adopted the principle of enforcing his creed by arms, instead of mere persuasion. We have not space to dwell on his victory over the *Hawazin* at Honayn: his precepts will fall under later sections. In 632 his health began to decline. He had always been subject to fits of epilepsy. This was long supposed to be a Christian calumny, and is so treated by Gibbon and others; but the researches of Weil have proved its truth. On the 7th of June 632, the sixty-third year of his age, Mohammed died of fever, his favourite wife, Ayesha, supporting his head.

In person Mohammed was of middle stature, with dark eyes, a ruddy complexion, and a fair and graceful neck. He wore a thick beard. His life was most simple: dates and water often his only food, and his house sometimes without fire for a month together. His manner, as well as his appearance, was fascinating, his conversation lively and not destitute of "that taste for humour which (as Dr Arnold remarks) great men are seldom without." He was fond of setting off the beauty of his person to the best advantage.

It must be owned that, apart from the Koran, there is a lack of contemporary written evidence for the life of Mohammed. Abulfeda lived in the fourteenth century; and Al Jannabi is also late, and a mere writer of legends. Later investigation has brought out the writings of Ibn Khaldoun, also of the fourteenth century, and of Tabari, who lived in the third century of the *Hegira*; and it is satisfactory to find that these authors do not apparently clash with what was already known. Dean Prideaux's *Life* (4th edit., London, 1708) is unduly hostile, and the *Vie de Mahomet*, by the Comte de Boulainvilliers, untrustworthy from the opposite cause. Gagnier's (Amsterdam, 1748) was the best of the last century. The account of Mohammed prefixed to Ockley's work seems fair, and more to be relied on than the main body of his book (*History of the Saracens*, 3d edit., Cambridge, 1757). Gibbon's famous fiftieth chapter is full and splendid; though Hallam, in an excellent discussion of the subject (*Middle Ages*, chap. vi.), rightly reminds us of the frail nature of a portion of the evidence. Dean Milman (*Latin Christianity*, bk. iv., chap. 1) gives a candid and masterly summary of the case.

Moham-
medanism.

Moham-
medanism.

He agrees with a distinguished French orientalist, M. Renan, in praising the copious work of Dr Weil (*Mohammed der Prophet, sein Leben und seine Lehre*, Stuttgart, 1843). Among minor works may be honourably mentioned *Lives of Mahomet and his Successors*, by Washington Irving, New York and London, 1850; and the Life published by the London Religious Tract Society. But the book to which we are here most indebted, and which can hardly be praised too highly, is the *Essai sur l'Histoire des Arabes*, &c., par A. P. Caussin de Perceval (Paris, Didot, 1847-48). Both M. Renan (*Revue des Deux Mondes*, tome xii, 1851) and Lieutenant Burton (*Pilgrimage to El Medina and Mecca*, London, Longman, 1855) sanction this admiration. M. Renan, it may be observed, cautions us against lending attention to Turkish or Persian, as distinct from Arab, accounts.

It remains to speak of Mohammed's character. Men's views have been largely influenced by preconceived notions. Thus, e.g., Voltaire, disliking religious fervour of any kind whatever, detested the memory of Mahomet (we adopt for the moment the French and English corruption of Mohammed's name), and has done his utmost to vilify him both in verse and prose. His tragedy of *Mahomet* is utterly unsupported by history. Of his arguments we may speak presently. Other writers have been favourable from indifference or hostility to Christianity, as Boulainvilliers, and possibly, in some degree, Sale and Gagnier. Among those who are too favourable we should be inclined to class Mr Carlyle (*Heroes and Hero-Worship*) and Mr E. A. Freeman, in his *Lectures on the History of the Saracens*. But if undue favour be now the chief danger, it has arisen from the reaction caused by the harsh treatment of Bibliander, Hottinger, Maracci, and Prideaux, from the sixteenth to the eighteenth century. Caussin de Perceval and Milman are very fair. But perhaps the most equitable and philosophic treatise is the short essay (50 pp.) of Möhler (*Ueber das Verhältniss des Islams zum Evangelium*), published in 1830, and re-edited by Döllinger in 1839 (Regensburg). A very correct English translation, by the Rev. J. Menge, has been issued at Calcutta (Ostell & Lepage, 1847).

The controversy concerning Mohammed's character turns mainly upon these two points: Was he a mere impostor? Was he, prophetic claims apart, a bad and immoral man? The believers in his entire or partial imposture allege the syncretistic character of his creed, and its bitter hostility to Christianity; the stains of voluptuousness and revenge which disfigure his character; and, above all, the supposed revelations about the cases of Maria and Zeinab. But none of these arguments are decisive. That his creed is largely borrowed from Judaism and Christianity does not prove that he was not honest in selecting what appeared to him to be truth. He never pretended to be teaching a new religion. The enmity to Christianity is a more serious feature. It certainly, in our judgment, convicts Mohammedanism of containing a seed of evil and bitterness through its false claims; but it followed logically, as we shall see hereafter, from the delusion of Mohammed in imagining himself the prophet of the human race, and delusion need not be hypocrisy. Of Mohammed's revengeful spirit and voluptuousness it must be said that we reason unfairly when we judge of them by a Christian standard. The assassination of his Jewish enemies was a fearful crime; but it neither shocked himself nor his companions, for Arabian morality, unhappily, did not condemn it. For a full discussion of the case of Zeinab and Maria, we must refer the reader to Möhler's Essay. Certain it is, that Mohammed's passions offended those around him as little as his revengefulness; he could boast of his physical powers, and record those things which are his shame, without a blush. But Möhler's remarks on this subject deserve the deepest consideration:

Moham-
medanism.

"I maintain, that if one admits the possibility of any man's being able to give out his own individual religious impressions, ideas, and thoughts, without suspicion, for divine inspirations, I cannot perceive the impossibility of his considering God also to be the author of all his other inward impulses." The learned writer then refers to religious rites practised in ancient Babylon (Herodotus, i. 199), and in many other countries, as a proof that men may come to regard the basest deeds as allowable, and even divinely authorized; and while fully admitting how much the above transactions lower Mohammed's character, and lend a plausibility to Voltaire's inventions and Goethe's imitations of them, he not unnaturally argues that Mohammed may still have acted with good faith, and would never have immortalized these events by the publication of the two chapters of the Koran, if he had been conscious of wickedness. No Moslem ever appears to have found any difficulty or inconsistency with Mohammed's prophetic character in these circumstances. (Möhler, ed. Doll., pp. 367-8.)

On the whole, then, while we regard Mohammed as a false prophet, whose teaching and character (amidst much that is good and true) contains most unchristian and anti-christian elements; while we consider his intellect to have been in many respects narrow and limited; while we leave to the Judge of all men the solution of the problem of his heart, with its admixture of lust, revenge, shamelessness, and apparent love of spiritual rule, strangely combined with its loftier qualities, we are unable to regard him as a bad Arab or a mere impostor. Of the Koran we shall speak presently. But on the whole, looking at the natural workings of an ardent imagination, exalted by meditation and solitude at a time when his countrymen were in an unsettled religious state; the conviction wrought upon those nearest to him, as Kadajah, Omar, and Abu-Beker; his endurance for twelve years of every species of insult and persecution; his steady rejection of every offer of wealth and chieftainship, made on the condition of his desisting from his endeavours; the simplicity of his mode of life to the very last;—we cannot accept the views of Voltaire, or of Prideaux and Maracci, but must so far side with Möhler, Caussin, Carlyle, Irving, and others, as to believe in the general sincerity of Mohammed, and his faith in himself and his own mission.

2. *The Probable Causes of Mohammed's Success.*—Some Mohammedan, and more especially Turkish, historians decline to investigate secondary causes of events, content to assert that such was the will of Providence. We are tempted to follow their example with respect to the question here at issue, so inadequate do the reasons usually assigned appear to us. Still, some of them may be true so far as they go, and it is right to mention these.

Arabia, Mohammed's native country, had enjoyed remarkable freedom. Even Gibbon admits that no conquest had been more than local or temporary. Hence arose great freedom of thought. The Arabs were a Semitic race, partly descended from the son of Eber, variously called Kahtan, Yectan, Jocktan (Gen. x. 25-30); partly from Ishmael, the son of Abraham by Hagar. Whether the Koreish were from Ishmael or from Joktan has been hotly disputed. Mr Forster, author of *Mahometanism Unveiled*, is strenuous for Mohammed's descent from Ishmael; and Caussin de Perceval seems inclined to support him. Dr Sprenger, one of the most recent biographers, takes the other side; as do Gibbon, Lieutenant Burton, and others. We do not attach great importance to this point. Mr Forster is probably biassed in one direction, as Gibbon is assuredly in the other; but all would probably admit, firstly, that the entire nation displays similar characteristics to the Ishmaelites in their love of fighting and plunder, varied by a taste for commerce (compare Gen. xvi. 12, and xxxvii. 25-28, with Judges viii. 24); and secondly, that Mohammed

Moham-
medanism.

himself claimed descent from Ishmael, and acted upon his belief. The ancient religion of Arabia has been proved to have been a strict Monotheism (Caussin, Renan, Hallam); and in maintaining that he was recalling his countrymen to their old creed, and appealing to the example of Abraham, he named one whose memory was honoured alike by Joktanite and Ishmaelite, Jew and Christian. The Arab is allowed, both physically and intellectually, to be a fine specimen of the human race, and it is to their natural qualities, their courage and energy, that many attribute their success in imposing their creed on other nations.

At the time of Mohammed's appearance there were Christian tribes, Jewish tribes, and pagan tribes. But Christianity seems to have been but imperfectly accepted even by those who professed it, and almost every imaginable form of heresy was rife in the Arabian Peninsula. A vague syncretism was very common, and there was a yearning for something more simple, definite, and dogmatic. Four of the Koreish (Caussin) had already tried to amend matters. Of these four, three ultimately became Christians; but the fourth, Zayd, son of Amr, was quite a precursor of Mohammed in his attack upon idolatry and proclamation of the Divine unity.

Some will at once attribute Mohammed's success to the use of the sword and the permitted indulgence of voluptuousness. As regards the compulsion by war, we answer with Mr Carlyle, that before you convert with the sword you must first get your sword. However much the creed of Islam may have been forced upon unwilling nations after Mohammed's death, there was certainly no violence employed in the first instance. On the contrary, physical force was in the outset against Mohammed. The supposed attraction of a sensual paradise, and permitted indulgence in this life, as a cause of success, has been sanctioned by Gibbon, who (it may be observed) inclines to think Mohammed hypocritical in his later days. But we quite agree with Mr Hallam and Mr Maurice (*Middle Ages; Lectures on the Religions of the World*, London, 1848, 2d edition) in thinking that the influence of such motives has been much exaggerated. Mohammed did not introduce polygamy; he found it in existence, and restricted it. He condemned all adulterous and incestuous connections; forbade wine, usury, games of hazard, superstitious divination by arrows, the sadly common sin of destroying female infants, and all war between tribes which had become Mussulman. When we add to this the fasts, the pilgrimages, and the regular prayers and ablutions enjoined by him, it will be hard to prove that the adoption of the new creed was thought to be an acquirement of more license either of thought or action. M. Caussin's narrative seems to us to establish the direct contrary (*Histoire, &c.*, tom. ii., pp. 402-3, 604). This point, with others, is also discussed in a pamphlet by the present writer (*Mahometanism*, London, Mozley, 1856.)

There remain the following probable causes of success:—The state of Arabia at the time of Mohammed's appearance—the actual amount of truth taught by him—the principles acquired directly or indirectly from Christianity—the points of contact with the past, and the religions then obtaining in his country—the remarkable elegance and purity of the Arabic diction of the Koran, and its applicability to law and the practical business of life—the native vigour of the author's mind, and the apparent need, to human eyes, of some great scourge upon idolatry. These causes may all have contributed to the result; but we cannot pretend that they seem to us to afford a complete and satisfactory explanation of the triumphant progress of Islamism in its early stages, still less of its extraordinary permanence in an almost unchanged state to the present day. With one more reflection we quit this branch of the subject. Those who consider Mohammed to be a conscious

Moham-
medanism.

deceiver place one more difficulty in the way of accounting for his success. "How, indeed, is it possible," asks Möhler, "that a religious fire, wild though it were, which in so astonishingly short a period set all Asia in flames, could proceed from one in whom the kindling material had no real existence?" Unless, which remains to be seen, Mormonism should prove an exception, we cannot call to mind an instance of any lasting religious effect being produced by a teacher who did not believe, however delusively, in the truth of his own mission and doctrine.

3. *The Koran*.—Neither with reference to the Koran, nor to the other claims of Mohammed, do we think it necessary to enter upon any formal refutation. Enough for us to observe, that the proper proofs of a Divine revelation are miracles and prophecy, and that Islamism possesses neither the one nor the other. There does not exist one authenticated account of a miracle wrought by Mohammed (indeed the Koran admits that he had no such power); nor is there one real prophecy, unless we call the threat against the overthrow of Persia prophetic, in which case we must extend the title to any warrior or statesman who makes a happy political guess. Thus Burke prognosticated, in the early stage of the French revolution, the advent of some military chieftain who should seize the reigns of power; and Napoleon foresaw the likelihood of a union between France and England to prevent the designs of Russia upon Constantinople. Other weak points of this false religion will appear as we proceed. At present we will only ask with Pascal, in his famous *Pensées*, what one mystery Mohammed revealed which was previously unknown? what miracle he wrought? and where this last prophet of the world was himself foretold? We pass on to a few brief notices of the Koran.

This work is divided into 114 chapters. They are of very unequal length, some of the longer ones being equal to at least ten or twelve of the shortest. It was revealed at intervals, and not collected into one body until after its author's death, when Abu-Beker acted as editor, and gathering together its portions (some written on skins, palm leaves, and blade-bones, and some few treasured up in the memory of disciples), placed as a rule the longest chapters first and the shorter at the end. This remarkably simple but not very philosophic plan of arrangement lends no aid to our comprehension of the doctrines of Islamism.

Its leading features are,—the assertion of the unity of God and the apostleship of Mohammed (which are the two great dogmas of Islam); its denunciations of idolatry and recital of legends illustrative of the Divine wrath against that great sin; its recognition of previous prophets, as Adam, Noah, Abraham, Moses, and Jesus, as also Ishmael and other minor ones, all forerunners of Mohammed; its accounts of angels, Gabriel and Michael, Azrael the angel of death, and Israfil, who is to sound the trumpet at the last day; of the fallen angels and their prince Eblis (Satan); of the Genii, a class of beings inferior to the angels; of heaven, hell, and the partition between called Al Araf; and of final judgment to come. The fall of Eblis and the fall of Adam; the flood of Noah and the life of Abraham; Sodom and Gomorrah; Isaac and Jacob; the guilt of Pharaoh and the plagues of Egypt; the rod of Aaron, the acts of Moses, the golden calf, the manna and the quails; Samuel and Saul; David and Goliath; Job, Jonah, and Solomon;—all these find their place in its pages, though sometimes in a very distorted guise. When we add to these certain evangelic ideas and precepts to be spoken of hereafter, and consider to what dimension the Koran would shrink if deprived of all that can fairly be traced to Holy Scripture, we feel the justice of Möhler's dictum, that "without Moses and the prophets and Christ, Mohammed is simply inconceivable; for the essential purport

Moham-
medanism.

of the Koran is derived from the Old and New Testaments." Respecting our Lord and Saviour, Mohammed teaches that, though only a man, he was miraculously born (chap. iii.), and that he wrought numberless miracles; and, apparently from a belief that it was unworthy of Christ's dignity to be put to death, he denies (chap. iv. *et alibi*) the reality of his crucifixion, asserting with the Gnostics, that another was put to death for him. Denying the doctrine of the Holy Trinity (which he quite misunderstood), the incarnation, and the atonement, he yet calls Christ the Word of God, the Spirit from God, announces His second advent and triumph over Antichrist, and teaches the doctrine of the Millennium. But these acknowledgments appear intended to exalt the dignity of Mohammed himself and the excellency of the Koran. Its own greatness is loftily proclaimed throughout the book; unbelievers are challenged to produce ten pages like it, and orthodox Mohammedans declare its substance to be eternal and uncreated.

It must not be overlooked that Mohammed felt deeply that the advent of such a teacher as he claimed to be *ought* to have been foretold. Hence the Koran, while recognising the Divine authority of the Pentateuch, Psalms, and Gospel, frequently (chaps. ii. and iii.) charges Jews and Christians with corruption of their own sacred books, and the withdrawal of passages which foretold him. His followers have since claimed certain texts, of which the most curious are,—Deuteronomy xxxiii. 2, where (in defiance alike of context and geography) Mount Sinai, Seir, and Paran, are wrested into respective predictions of Judaism, Christianity, and Mohammedanism; and Isaiah xxi. 7, where the Vulgate rendering, *Ascensorem asini et ascensorem cameli*, is made to refer firstly to the Prophet of the Gospel, and then to the Prophet of the Koran. A third passage is St John xvi. 7, apparently alluded to in the 61st chapter of the Koran, the promised Paraclete being interpreted to mean Mohammed (just as the followers of Manes had referred it to him); a blasphemous view, though not intentionally such. Mohammed, confounding and identifying the Holy Spirit with the angel Gabriel utterly mistook the drift of this prophecy.

Among popular errors must be named that of supposing the Koran to deny that women have souls. On the contrary, paradise is promised to those who believe and do aright (chaps. iii. and iv.) It must also be remarked, that the idea of paradise contained in it, though gross and carnal, is less so in the book itself than in the pages of its Moslem commentators.

Of the civil laws in the Koran relating to marriage, inheritance, slaves, contracts, murder, theft, &c., we must try to speak in subsequent sections. We may just notice its establishment of the month of fasting (Ramazan), and a weekly holiday (Friday), in memory of man's creation; its prohibition of usury and of swine's flesh; and its high commendations of the duty of prayer. Penitence is also praised, and in some cases slight and reasonable penance is enjoined.

To a European reader, even if partial to Mohammed's memory, the Koran, in a translation, is for the most part hopelessly wearisome. Even Gibbon has observed how completely the single book of Job, in a mere literary point of view, eclipses it. Its Judaic character may in part be guessed from the above sketch. With some exceptions it bears the impress of "a spirit bounded and poor," yoked to much that is local, national, and temporary, as distinguished from that which is of universal application. This might of course be in part applied to Judaism likewise; but then Judaism was but preparative, and did not pretend, like Islamism, to be a universal religion. In each case (not of course that we class the two together in any other respect) the vehicle of a Semitic language probably of itself imposes certain limits. Unsurpassed in the expression of simple and pathetic narrative, wise moral precepts, and that which is sub-

Moham-
medanism.

lime and awful in devotion and denunciation, the Semitic tongues have never been the medium of any very *original* subtlety in argument and preciseness in definition. In its finer parts the Koran reminds us of prophets rather than evangelists: *e. g.*, "God! there is no god but He, the living, the self-subsisting; neither slumber nor sleep seizeth Him; to Him belongeth whatsoever is in heaven and on earth. Who is he that can intercede with Him but through his own good pleasure?" (chap. ii.). Of the purity of its Arabic, and of its effect upon the oriental mind, there seems to be but one opinion. Nor do its deficiencies, as its narrowness and lack of all mysticism, affect the sincerity of its author. We can recognise in it, with Möhter, "an original piety, a touching devotion, and a thoroughly individual religious poetry, which cannot possibly be forced or artificial;" and add too, with him, "that many millions of men feed and foster from the Koran an estimable moral and religious life; and one cannot think that they are drawing from an empty spring, from the composition of a mere deceiver."

For fuller information on the Koran, the reader is referred to the excellent translation of Sale, with its valuable notes and introduction. The first edition appeared in 1734, and has often been reprinted. It had been anticipated by a Latin translation (to which Sale acknowledges great obligations) by Maracci, professor of Arabic at Rome, published at Padua in A.D. 1698, with a very learned but too hostile *Prodromus* and *Refutatio Alcorani*. These last have the verses marked, and are consequently more convenient for reference than Sale's. On Mohammed's borrowings from Judaism Milman recommends a prize essay by Geiger, rabbi of Wiesbaden, — *Was hat Mohammed aus dem Judenthum genommen?*

4. *Other Elements and Characteristics of Mohammedanism.*—A book once received as sacred implies the existence of teachers and of commentaries. These are greatly needed in the case of the Koran, which, by the admission of Mohammedans, contains 225 contradictions (Renan, Prideaux, and Milman); *i. e.*, 225 passages which were abrogated by fresh revelations. The principle is asserted in the Koran itself:—"Whatever verse we shall abrogate or cause thee to forget, we will bring a better than it, or one like unto it" (chap. ii.).

Islamism has both teachers and commentaries. Thus, *e. g.*, in Turkey, the body of the *Ulema* (corresponding to divines and jurisconsults in Christendom) is appealed to by the Sultan respecting the right application of precepts of the Moslem faith; and their decision is known as a *fetua*. M. Ubicini (*Lettres sur la Turquie*, Paris, 1853) gives a specimen of a *fetua* of recent date, A.D. 1839. It is directed against the famous Méhémet Ali, then in open revolt against his sovereign. The Sultan demands whether the authors of the rebellion may not be justly regarded as impious men, who defy the precepts of the Koran, &c. The replies, signed by forty doctors of different degrees, are entirely favourable to the Sultan's view of the case, and sanction the most extreme measures.

Not less important is the supplement to the Koran, known as the *Sonna*. This mass of traditions and oral law was fixed and sanctioned about 200 years after the Hegira. The *Sonna* embodies certain sayings and acts of Mohammed not contained in the Koran. The wives of the founder of Islam, and the four first caliphs, were the main authorities appealed to by its editor, Al Bochari. But though carefully compiled, it is in part apocryphal, as was likely to be the case. Its general tendency is to mitigate the sternness of the Mohammedan creed, to amplify and render it somewhat less local and temporal, and adapt it to a later state of things. The *Sonna* does not dogmatize on the Divine nature or attributes, but bears rather upon practical life, in which, next to the Koran, it is the great source of customs. It also contains some weighty sentences on faith,

Moham-
medanism.

on works, and on penitence,—the last being highly lauded. It follows the Koran in its rigidity on the subject of the Divine predestination.

Of other features of Islamism, not arising directly out of the Koran or the Sonna, we can here only find room to speak of two,—its dervishes and the element of mysticism.

The Koran is decisive against asceticism; nevertheless, partly from oriental love of contemplation, partly, perhaps, in imitation of the Christian communions with which it was brought in contact, Islamism has long had its bodies of dervishes. They are apt, however, to break away from the faith and practice of the religion which they profess. It is a common notion that madmen and idiots are specially gifted, and see more of things heavenly, because deprived of earthly reason, and undisturbed by external objects. This opinion has led to great abuses, as it is no uncommon thing for a dervish to feign madness with a view to spiritual reputation, which is, again, in many cases a stepping-stone to political power, sometimes even to a throne. Thus, towards the close of the eighteenth century, Bagian obtained among the Turcomans, whose capital was Bochara, supreme authority, first in religion, then in the state; and the dynasty of the Sofi, which lasted 230 years in Persia, was founded in the same manner. Power thus acquired has a fair chance of descending, as Mohammedanism cherishes the idea of religious sanctity being hereditary. On the other hand, mere intellectual gifts have seldom won such advancement for their possessors.

Still more alien, if possible, from the original spirit of Islam is the idea of mysticism. This has been disputed or ignored, but the evidence is quite overwhelming. Ancient Arabian poetry knows nothing of mysticism; the Koran is utterly devoid of it. It has found its way into the religion through the influence of countries conquered by the Moslem, more especially of Persia, where the national poetry has ever been pervaded by a thoroughly mystical tone. This element, commonly known as *Soffeism*, is still conspicuous in the works of Turkish and Persian poets. But as its leading idea is that of union between the creature and the Creator,—and this in a pantheistic manner, which, like Buddhism, Brahminism, and similar creeds, tends towards the denial of the Divine personality,—*Soffeism* is most abhorrent to the true genius of Islamism, and is decidedly condemned by orthodox Mussulman theologians. On this last point see M. Renan, Taylor's *History of Mohammedanism*, and *Persian Literature* (by Mr Cowell) in the *Oxford Essays* for 1855. On the section in general, and on most of what follows, the reader will find much compressed information in a very masterly essay by the late Dr Döllinger,—*Muhammed's Religion nach ihrer innern Entwicklung und ihrem Einflusse auf das Leben der Völker*, Ratisbon, 1838. Its chief blemish is an occasional want of discrimination between real characteristics of Islamism and features common to other oriental religions. An Italian version has been published (Milan, G. Silvestri, 1848). This article is deeply indebted to Döllinger's essay.

5. *Its Social and Political Features.*—The social life fostered by Mohammedanism requires perhaps a more dispassionate investigation than it has yet received. It is not enough to show its inferiority to Christianity in this respect; it ought in fairness to be confronted with other false religions. F. von Schlegel, though by no means favourable to Mohammed or his religion, yet allows, in his *Philosophy of History*, that its moral code is higher than that of Buddhism. Respect for women was not unknown to the pre-Islamite Arabs, and Kadijah and Ayesha are in honourable remembrance with the followers of Mohammed. Still, however, the blight upon woman's lot, which is only removed by Christianity, presses heavily upon the weaker sex throughout all Moslem countries. Although a large proportion can

Moham-
medanism.

only afford to keep one wife, yet polygamy, to the extent of four wives, besides concubines, being sanctioned by religion, is beyond the reach of attack. And women are certainly regarded as a subaltern class in a state of virtual servitude. Their religious education is limited to a mechanical knowledge of prayer; they are forbidden to attend the worship in the mosques; and jealousy precludes them from the visits of any religious teachers. Their paradise is supposed to be different from that of men; and a devotional life is almost unknown. There is no religious ceremony of marriage; and in this, as in her entire social *status*, the Mohammedan wife is probably in a position inferior to that which was enjoyed by an ancient Roman matron. Far more vast is, of course, the gulf between the women of Islam and of Christianity, of which all the chief communions can display such noble specimens of piety, heroism, and intelligence. The harems are but too often a stage for the development of bad passions, as envy, jealousy, and unnatural crimes. Abortion is so common as to have affected the population in some countries, as Turkey; nor is it punishable, if the master of the household have given his consent. Sons by different mothers are constantly rivals, and their jealousies have often rent in pieces the fabric of Mohammedan states. The most stable of Islamite government—the Ottoman—is supposed to have owed its endurance in great measure to the circumstance that Mahomet II. made fratricide a law in the imperial family; and the Sofi in Persia used regularly to put out the eyes of princes not destined for the succession. Nor is the influence of wives able to restrain rulers, as Christian princesses have often done, from acts of cruelty. One noble but solitary exception is recorded,—that of Zobeide, wife of the celebrated Haroun Al Raschid.

The extreme facility of divorce is an evil as great as that of polygamy. It is in some degree checked among the wealthy by the provision that the wife's dowry must be restored, and in Persia the feeling of the higher classes is said to be against it. Still the practice is fatally prevalent, and induces a low and degrading tone about all that concerns the matrimonial relation. Above all, the rebukes uttered by St Paul in the first chapter of his Epistle to the Romans (verses 26–28) are but too applicable to the moral condition of most Mohammedan countries, and more particularly of Turkey.

Another feature in the social life of Islamism is that of slavery. Whatever difference of opinion on this head may exist among Christians, few will be found to assert that the principle of slavery is recognised by Christianity as an enduring institution; and none will deny that the abolition of slavery in Europe is attributable to the influence of the gospel. Now, Mohammedanism recognises the principle, and this is surely so far a blot upon its character. Nevertheless, when this is once admitted, the highest commendation must be bestowed on the humanity of many of the provisions for the treatment of slaves. Mohammed from the first put slaves under the protection of his creed. He taught that they were brethren, equally created by God, and that good or ill treatment of them would seriously affect an owner's prospect of paradise. A master who chastises without cause ought to let that slave go free; liberation of slaves is at all times a good work; a female slave cannot be, without her own goodwill, separated from her child; and if she have borne a son to her master, must be set free. The most recent travellers (*e.g.*, Burton) fully confirm the reports of earlier observers. They tell us that a slave who is dissatisfied can legally compel his master to sell him. It is not merely possible, but even common, for a Mohammedan slave to rise to the highest offices. Lieutenant Burton travelled with a pacha who had been the slave of a slave, and of whom a Turkish officer remarked,—*C'est un homme de bonne famille, il a été acheté*. It is true that

Moham-
medanism. the history of Islamism in the East records many insurrections of slaves; but these do not appear to have arisen from bad treatment, as was the case in ancient Rome; they have resulted rather from occasions of general turbulence and religious excitement.

A complete survey of the political features of Mohammedanism would require some account of their conquests. Our limits forbid such an attempt; and the reader must be referred to Gibbon, D'Herbelot, Ockley, Von Hammer's *Ottoman Empire*, the *Histories of Mohammedanism* by Mill and by Major Price, and Mr E. A. Freeman's recent *History and Conquests of the Saracens*, for fuller information. Enough for us to recall that Persia, Syria, Egypt, Africa, and Spain, were rapidly overrun by the Saracens (as the Arabs from some unexplained cause were called in the West); and that within a century after the Hegira, the caliphs had become, in the language of Gibbon, "the most potent and absolute monarchs of the globe." While, however, idolaters were exterminated, and their temples overthrown, a certain amount of civil and religious liberty might be secured, on submission and the payment of an annual tribute, "by the people of the book;" i. e., those who possessed, or claimed to possess, a written revelation from Heaven, as the Jews, Christians, and Magians (or Ghebers), the fire-worshippers of Persia. We can only add that the famous victory over the Saracens, gained by Charles Martel, between Tours and Poitiers in A.D. 732, alone, humanly speaking, saved European Christendom from utter ruin; that the most flourishing period of Moslem rule in Spain was under Abderrahman in the tenth century, and the conquest of Hindustan by Mahmood was nearly contemporaneous; that the Crusades lasted from 1095 to 1270; that Constantinople was captured by Mohammed II. in 1453; while, on the other hand, the great checks of the sea-fight of Lepanto, and of the defence of Vienna by Sobieski, occurred respectively in 1571 and 1683. Since that time, the Ottoman Empire has steadily declined. The formation of the kingdom of Greece in 1829, and the Anglo-French alliance in the war of 1854-56 are too recent to require notice.

It is more in accordance with the object of this article to touch upon some of the *principles* of Mohammedan rule. The patriarchal union of spiritual and regal power in one and the same person was exhibited by Mohammed and by his successors the first caliphs. So indissolubly were the two supposed to be connected, that a division of the empire among the ruler's sons (like that of Charlemagne) was held to be quite inadmissible. The caliphate, which was at first elective, soon became hereditary. But as Mussulmans scarcely seem to recognise the difference between events ordered by the Almighty and those merely permitted by Him, the doctrine that *might makes right* was soon admitted, and the claim of a successful usurper was easily recognised. One condition is indeed a *sine quâ non*, and that is, that Mohammedans *must* be governed by a co-religionist. They could not, as Christians may, submit to a heathen sovereign; indeed, all Christian princes are regarded by the Moslem as usurpers. The great monarchs, as in Turkey and Persia, are (as has been intimated) among the most absolute on earth; all property theoretically belongs to them; their conduct is considered to be beyond scrutiny, and above the ordinary laws of morality. Their power over life and death is unlimited; and though the mass of the populace are rarely touched, yet some idea of the perilous state of those about the court may be formed from the fact, that in the space of 419 years (from 1370 to 1789) Turkey saw 138 viziers, of whom a large portion fell by the hand of the executioner. Nor does such severity lower a sultan in general estimation: many of the most esteemed (e.g., Soliman the Magnificent) have been among the most sanguinary in their executions. It must, however, be remarked, that no Mohammedan ruler has ever succeeded in

changing, to any great or lasting extent, the religion of his subjects; and in this particular, as in so many others, they stand in marked contrast to Christian princes, as may be seen in the history of national conversions to Christianity and the epoch of the Reformation in Europe. The emperor who among Moslems approached nearest to such influence was the famous Akbar, sovereign of Delhi, contemporary with our Queen Elizabeth. But Akbar cannot be regarded as a sincere Mussulman; his belief was rather that of a rationalistic deist. On the other hand, the repression of any nascent heresy by the sword is in thorough harmony with the general spirit of Islamism; and the degree of interference with the minor details of life and worship, and with questions of doctrine, far exceeds anything known in Christendom.

The cruelty too often exhibited in Moslem legislation does not arise out of the enactments of the Koran, which is decidedly lenient in its tone. Homicide, with malice aforethought, adultery, and apostacy, are the sole crimes recognised as capital by the Koran; and in the case of adultery a fine was soon substituted. It appears more probable that cruelty has arisen from that subtle connection with lust, which has frequently been commented on by moralists. In cases of rival dynasties the severities have been tremendous on both sides. Price relates that Aba-Moslem, who established the Abbassides in the caliphate (A.D. 750), killed (besides those who perished in battle) 100,000 persons to consolidate the new dynasty; and the death of the famous Hossein, son of Ali, was revenged by the execution of 48,000 men. It is acutely remarked by Döllinger, that scarcely ever did a Christian prince on his deathbed recommend a crime, or even an execution; whereas among Mohammedan rulers such an event is by no means uncommon,—so much less hold upon the conscience does Islamism possess than Christianity, though both tell of another world and a judgment to come.

It is remarkable that upon the whole the Moslem dynasties have been among the most unstable in the world. With the exception of the Abbassides, the Sofi in Persia, and the rulers of the family of Osman in Turkey, the changes have been rapid and extreme. The hereditary principle is generally less likely to be strong in countries where polygamy is sanctioned. In Persia during nine centuries (i.e., from the ninth to the eighteenth) fourteen dynasties reigned; other parts of Asia and Africa have undergone the same lot; and when it is considered that these changes have almost always been accomplished by violence, some idea may be formed of the contrast between the majority of Mohammedan thrones and those of Christendom.

For the social and political life of Islamism the works of travellers in Arabia, Turkey, Persia, &c., may be referred to with advantage. It will be sufficient to allude to such travellers as Burckhardt, Niebuhr the Elder, Malcolm, Chardin, Morier, Burnes, Fraser, Ouseley, &c., as having rendered important contributions to our knowledge. Among recent works we may specify Mr Lane's edition of the *Arabian Nights*, with its valuable notes, and Lieut. Burton's *Pilgrimage to El Medinah and Mecca*. We must also mention with high praise the spirited sketches of the Princesse de Belgiojoso, contributed to the *Revue des Deux Mondes* during the years 1855 and 1856; also the learned Dr Pocock's *Specimen Historiæ Arabum* (Oxon. 1806), to which Sale and Gibbon acknowledge their great obligations.

6. *Principal Sects.*—Almost immediately after the death of Mohammed a great dispute arose among his followers as to his successor. A strong party were in favour of Ali, already mentioned as Mohammed's son-in-law by his marriage with Fatima. But he was not chosen until after a lapse of twenty-three years, during which time the throne

Moham-
medanism.

had been occupied by Abu-Beker, Omar, and Othman. Nevertheless a tradition that the first three caliphs were usurpers, and that Ali had been grievously wronged, has prevailed to the present day among a large proportion of Mohammedans, and hence the primary ground of dissension between the Sunnites and the Shiites; the latter being the partisans of Ali, while the Sunnites accept the legitimacy of the first three caliphs. Other points of difference ensued. The Shiites place Ali at least on a level with Mohammed (a view which we suspect had reached Dante, judging from the twenty-eighth canto of the *Inferno*, lines 31, 32); the Sunnites imagine a vast interval between Mohammed and every one else. Some have supposed the Shiites to reject the Sonna entirely; but this appears to be a mistake. They refuse, indeed, to accept such parts as come from Abu-Beker, Omar, and Othman, or any other enemies of Ali, but they accept the rest, and moreover admit other traditions which are not recognised by the Sunnites.

Thus far this great schism appears to be of a purely personal and historical character. Even to this day, as Lieut. Burton witnessed, the Persian pilgrims to Medina will almost endanger their lives by muttering curses at the tombs of the three usurping caliphs (as the Shiites consider them) and weeping over that of Fatima. Still it is hardly possible that such rivalry and opposition could have lasted had the legitimacy of the succession been the sole point in dispute. The *kind* of regard given by the Persians to the twelve Imams, or descendants of Ali, involves a more real difference of doctrine; and, on the whole, it is reasonable to believe that a sort of under-current of the old Persian creed of Magianism (including some ideas of *mediation*) runs through the Shiite teaching. The strength of the Shiites lies in Persia; of the Sunnites in Turkey and its dependencies. In times of apathy they have been known for a brief season to dwell together, but in general they detest and anathematize each other as worse than Jews or Christians. We must profess our conviction that no impartial observer, whether regarding the case historically or doctrinally, can hesitate to conclude in favour of the Sunnites as the more orthodox Mohammedans. Gibbon, Taylor, and Burton all tend to confirm this view.

The Sunnites are again subdivided into four sects,—Hanefites, Malefites, Shafeites, and Houbalites,—named after their respective founders. These, however, all regard each other as orthodox in fundamental points. The remaining sects (to which we can do little more than allude, for a mere list of their names would occupy a large space) have arisen chiefly out of controversies on the Divine attributes, or on predestination (a very fertile source of schisms); on Antinomianism; on the rewards and punishments of the life to come; on the Mahadi or Medhi, the twelfth Imam looked for by the Persians as about to return as the overthrower of Degial or Antichrist in the latter days; and on mysticism. Inclinations towards Buddhism, and even towards Manicheism, have also given rise to fresh sects.

Perhaps the most important, certainly the most energetic, of recent sects have been the Wahabees, who arose towards the end of the tenth century. Their founder, Abdel Wahab, was a reformer who sought to bring back Islamism to its pristine condition under Mahomet and Omar. The Wahabees have been not unjustly called the Puritans of Mohammedanism. They protested against a practice which had gradually crept in of venerating Mohammed and other Moslem saints as intercessors; and tried to restore the rules of the Koran in many of the details of life. So great was their success, that for a time Mecca and Medina fell into their hands. They were ultimately put down by the Pasha of Egypt, but their principles are not extinct.

There has been no limit to the wildness and immorality of some of the Mohammedan sectaries; and the circum-

stance that Mohammed appealed to the sword has caused a constant recurrence to this *ultima ratio* on the part of any newly-formed school, and no less so on that of their opponents. The great schism between Sunnites and Shiites materially weakened, if it did not overthrow the caliphate; and for a time favoured the progress of the Crusaders; and Abdallah Ben-Tammurt, founder of the sect of the Mowahhedini in Africa (A.D. 1116), is said to have destroyed 70,000 persons. This is by no means a solitary instance; and in quitting the subjects of the sects, we can only express our astonishment at the gross ignorance of Spinoza, who asserted that the Mohammedan communion had known no schisms. Our chief authorities on this part of the subject are Sale, Döllinger, Gibbon, and Burton.

7. *Literature, Science, and Art.*—The Arabs before the time of Mohammed (or, as they term it, in the days of ignorance) excelled in poetry and oratory. Their seven prize-poems suspended (Moallakat) in the Kaaba, have been translated by Sir W. Jones, and display much spirit and beauty. But there is little reason to suppose that Mohammed was in any way a patron of general knowledge or of letters. Praises of science from his lips have indeed been quoted, but not until the dynasty of the Abbassides had begun to patronize letters; and their genuineness is extremely suspicious. His one act of interference in these matters was essentially anti-scientific. Shortly before his death he reinstated the vague old lunar calendar of Arabia (*Cassini*, iii., pp. 302, 303), and forbade the insertion of the triennial intercalary month by which it had been improved. The famous story respecting the second Caliph Omar, and the destruction of the library at Alexandria has indeed been called in question; but it does not appear to be intrinsically improbable, or at variance with the character of the early Mohammedans. As, however, their rule became more settled, a change came over them, and literature was abundantly patronized in Spain, and by the caliphs of Bagdad, more especially Haroun Al Raschid, the hero of the *Thousand and One Nights*, and Almamun. Nor can we deny that European Christendom is indebted to their labours. The nine numerals which effected so great a revolution in arithmetic were introduced by them. *Al-gebra* and *Al-chemy* both betray by their prefix the quarter from which Europe received them; nor is it possible to study a catalogue of the stars without being struck at the large proportion which, by the retention of Arabic names, testify to their successful cultivation of astronomy. Sismondi (*de la Littérature du Midi de l'Europe*) thinks that their poets influenced the taste of the Troubadours. Their commentaries on Aristotle, though often militating with their orthodoxy as Mohammedans, produced a great effect upon the mind of Europe. Even Dante names Averroes; and our great countryman Roger Bacon displays a most extensive acquaintance with the Arabian authors, particularly with Avicenna. Such men as Averroes and Avicenna deserve respectful mention in these pages, for they have not inaptly been termed *encyclo-pædists*, from the range and variety of the subjects treated by them. Medicine, though a less strong point than logic and metaphysics, was also cultivated by the Saracens. We must also take into account the Persian *literati*, especially the poets who have flourished since the introduction of Islamism, and the Turkish moralists and writers on jurisprudence. Nor must we fail to acknowledge the intellectual improvement caused in Africa, where the village possessing a Marabout or Mussulman teacher is always found to be far in advance of its neighbours in all the elements of civilization.

Of art we can say but little, for it is almost a blank in the realms of the Moslem. The prohibitions of the Koran against images are fatal to its culture; though a single exception, that of architecture, must be granted to the Spanish Arabs. A high authority, Mr Owen Jones, regards their

Moham-
medanism.

architecture as the legitimate offspring of the Koran, nor do the remarks of Lieutenant Burton appear to us to overthrow this supposition. But in any case, there can be but one opinion as regards the singular and original character of beauty which distinguishes the remains of the Alhambra.

Still, after all, it must be said that the Arabian genius was receptive rather than originitive; it handed on the torch of learning, but it did not give the quickening spark; its creative powers cannot be compared with those of Greece, nor its jurisprudence (shut up in the Koran) with that of Rome; while in algebra, &c., the Hindus are decidedly superior. Their science is a mass of borrowings from Euclid, Ptolemy, Aristotle, Galen, &c. In Persia the greatest poets were all actually or virtually pre-Islamite.

The research into Mohammedan literature is still incomplete. Mill's *Mohammedanism* (London, 1817), chap. vi.; Berington's *Literary History of Middle Ages* (London, 1814); and the literary portion of Mr Sharon Turner's *History of England* (vol. i., chap. v.), all afford information. M. Ubicini has a neat *resumé* of Ottoman literature (vol. i., let. x.); Mr Cowell's *Essay on Persian Literature* has been alluded to; Condé, *Historia de la Dominacion de los Arabes en España*, did much by first calling attention to the writings of the Moors in Spain, and though violently attacked for deficiencies in knowledge of Arabic, yet cannot be robbed of this praise. Much might have been expected from the distinguished historian of the Ottoman Empire, Von Hammer (subsequently Count Von Hammer-Purgstall), who before his death had commenced a work entitled, *Literaturgeschichte der Araber, Von ihrem Beginne bis zu Ende des 12 Jahrhunderts der Hidschre*, Wien, 1856.

8. *Its relation to Heathenism.*—The most impartial thinkers generally allot to Islamism a kind of half-way place between paganism and Christianity; somewhat as, in popular legend, the coffin of Mohammed was supposed to be suspended by loadstones between heaven and earth. If, in employing the term paganism, we think primarily of the religion of Greece and Rome, it must be allowed that the teaching of the Arabian is a great advance. Classic paganism was in constant danger of allowing its votaries either, with Epicurus, to deny any real Providence (a doctrine which practically amounts to atheism), or to fall into pantheism, and thus deny the divine personality and the enduring individuality of the soul. Above all, its polytheistic idolatry appears from Holy Scripture to have involved communication with evil spirits. (See Deut. xxxii. 16, 17; Ps. cvi. 37, 38; 1 Cor. x. 18–20.) Now, Mohammedanism, both by words and deeds, protests most vigorously against all these errors—Epicurism, pantheism, and idolatry. If, as we have seen, its dervishes have displayed a tendency towards pantheism, this is an intrusive element, and alien from the essential character of the religion. Far from encouraging the cloud of doubt which hangs around the question of Providence in classic writings (as, e.g., even those of Cicero), Mohammedans so thoroughly recognise the Almighty as the great originator of all things, as almost to shrink in their histories from the investigation of secondary causes. And as regards idolatry, that great day of Mohammed's life when he destroyed the idols of "The Square House," or Kaaba, at Mecca, was again and again reenacted by his disciples,—most strikingly, perhaps, in their famous conquest of Hindustan, where the idolatrous temples had become the haunts of the most appalling wickedness.

Nor is the superiority of Islamism to paganism confined to mere negations of error. On the contrary, it teaches positively and clearly much that paganism had lost, or was teaching but very vaguely. The unity of God, eternity and judgment to come, fixed rules of right and wrong, the existence of real revelations, the value of repentance,—borrowed these truths may be from Judaism and Christi-

Moham-
medanism.

anity, but however obtained, they are unmistakeably announced by Islamism. It appears, moreover, to be comparatively free from the self-righteous notions taught by other eastern creeds, as Hinduism,—for even Mohammed himself is held by orthodox Islamite theologians to have been admitted into Paradise through Divine mercy only, and not for his presumed good deeds. Lastly, it is conspicuous above all merely human forms of religion, for the sense of brotherhood with which it inspires its votaries. Mohammed appears to have deliberately aimed at this result, and his success has been truly wonderful. With the exception of caliph or sultan, all Mussulmans are regarded as spiritually equal; nor, indeed, is there any temporal superiority, except such as may arise incidentally from the possession of wealth or office,—a precarious superiority in the East, and one which the events of a single day may entirely reverse. Every Moslem is supposed, by spiritual filiation, to be grafted into the great Arab race,—a truly noble idea, beyond the teaching of Judaism, because reflected from the light of that faith for which Judaism was only a preparation. Hence his creed is, far more than his country or his race, the one object for which a Mussulman is prepared to labour and to fight.

Still, it must not be supposed that Islamism is, from every point of view, superior to the other false religions which it confronts. There are certain needs in the human heart which other creeds have at least attempted to satisfy, but for which Mohammed has nothing to offer. Pantheism, erroneous as it is, yet expresses the deep yearnings of men's spirit for union with his Maker. Even idolatry, with all its deep sinfulness, recognises the want of something to interpose between our fallen nature and the purity of an offended God. Magianism, Buddhism, and other forms admitting mysticism, find food for these wants: Islamism is essentially bare and arid, and leaves the gulf between man and his Maker in all its vastness. Even sacrifice cannot be considered as part of the essence of Mohammedanism. It is only (with some rare exceptions) performed on the occasion of a pilgrimage, and may be neglected even then on the condition of observing an additional ten days' fasting in the course of the year.

9. *Its relation to Christianity.*—Among the most striking inconsistencies of the Koran is the contrariety of its tone in different parts with reference to Christianity. In the second chapter Jews, Christians, and Sabians are all placed upon a level, and assured of salvation if obedient to the law of their respective creeds; but in the chapter which immediately follows, according to the existing arrangement, we are told that "whoever followeth any other religion than Islam, it shall not be accepted of him, and in the next life he shall be of those who perish." It would not be possible here to dwell upon the different modes of solving this difficulty which have been attempted; we can only, with the *Quarterly Review* (No. 186, September 1841), express our entire acceptance of the theory of Möhler, that Mohammed commenced his career merely as the prophet of Arabia, and gradually persuaded himself that he was the destined prophet of the world. So long as he regarded himself as the teacher of his own countrymen alone, he was willing to consider Christianity as a religion of co-ordinate authority with that which he taught; but when, extending his sphere of thought and action, he claimed the universe as the scene of his mission, he was compelled to represent Christianity as subordinate to the creed of Islam. Now, however sincere Mohammed may have been in his delusion, the part of a universal instead of a merely national instructor involved far larger demands (if the expression may be permitted) upon his creed and character. But of this he does not seem to have been at all conscious. It behoves us, however, to consider some of the leading points of distinction.

Moham-
medanism.

That a national religion should be inseparably bound up with the state appears natural, and is perhaps almost inevitable. It is certainly part of the normal condition of Judaism when flourishing. But a religion which is to be the heritage of all mankind must be capable indeed of coalescing with any rational form of government, but no less capable, if need be, of standing in the completest isolation from the state. Now, Mohammed's religion includes in itself the idea of a universal monarchy. This condition alone must necessitate the failure of all its attempts to become a religion of the universe; and even in Mohammedan countries, though originally an element of strength, it tends to produce ultimate decay. Without entering into details, it is obvious that strict adherence to the Koran, as the law of the state, must impede many reforms which in a political aspect may become highly necessary.

Again, while we admit that Christianity has at times employed the sword as an instrument of defence, or even a means of conversion, still the instances have been comparatively rare and exceptional; but in the case of Islamism the exception is the other way; its votaries almost avow that too long peace endangers its vigour and vitality. And thus Mohammedanism has no real claim to be a religion of love: it cannot even imagine that union of special favour to its own with benevolence to all, which is one of the first lessons of Christianity.

But, above all, did Mohammed fail to comprehend the lofty requirements needed for a teacher of humanity at large. A good Arab he may have been, according to the miserably imperfect standard of his age and country; nevertheless he was a man blood-stained and lust-stained, and, moreover, unrepentant of these sins, because unconscious of their shame. But the prophet of the universe must soar far above all merely conventional morality; he must satisfy *all* the really religious needs of the human heart, and such needs can find their satisfaction in nothing else save the mystery of an Incarnate God, alike the teacher and the redeemer of the world. Mohammed's celebrated declaration, "There is no God but God, and Mohammed is the apostle of God," combined a solemn and vital truth with a hopeless and tremendous falsehood. Against superstitions worse than his own that truth held its way triumphantly, but before Christianity it was sure in the long run to pale and wither. It has its warriors, but hardly martyrs; and polygamy must be fatal to its universality, for polygamy can never satisfy the needs of woman's heart.

And while with Dante (*l. c.*), Jones, Leibnitz, De Maistre, and others, we may admit that the amount of truth contained in Islamism renders it more like a heresy than an absolutely false religion, yet we submit that, as regards its view of the person and office of Christ our Lord, and its doctrine of a unity of person (not of substance merely) in the Godhead, there is a greater gulf between Mohammedanism and Christianity than is always, or perhaps usually, admitted. Moreover, the doctrine of the Divine unity and omnipotence becomes unspeakably different when viewed apart from, or in connection with, the idea of an all-perfect Mediator. It is apparently the unsoftened awfulness of that doctrine in its lonesomeness that causes the deep melancholy observed in so many of the more earnest Mohammedans. And even as regards predestination, on which so many Christians appear theoretically to agree with the Moslem, it could, we feel assured, be shown that Mohammedan submission under reverses is, with all its acknowledged merit, something very different from Christian resignation, and far less noble and ennobling.

Lastly, in its lack of any one good thing in which Christianity has not anticipated it; in its constrained spirit and

absence of any real sympathy with progress and the highest forms of civilization; in its spiritual and intellectual poverty and limitation to oriental or African regions,—Islamism betrays the limited and finite conceptions of a merely human author, and stands in marked antithesis with the faith of Christ.

On these points there is something to be gained from White's *Bampton Lectures*, Oxford, A.D. 1784; also from *Lectures on the History of the Turks in its relation to Christianity*, Dublin, 1854. The author of the last named writes, however, it must be observed, with a Roman Catholic object in view.

10. *Its present Condition and probable Future.*—The creed of Islam is still very widely spread. It is professed throughout the Turkish empire, Persia, Arabia, Russian and Independent Tartary, Madagascar, parts of the eastern coast, and the interior of Africa, by a large part of the population of Hindustan, and in the islands of the Eastern Archipelago. The Malay tribes appear to take an active part in spreading Mohammedanism; and all Christian missionaries (though frequently acknowledging the improvement thus wrought among idolatrous populations) agree in deploring the extreme difficulty of converting Moslems to the faith of the gospel. At the Cape a few cases have occurred of professing Christians lapsing into Islamism; but some have happily been reclaimed. In China, the prohibition of swine's flesh is said, with every appearance of probability, to militate against the reception of the Koran. The number of Mohammedans has been variously stated from 100,000,000 to 140,000,000. We should suppose the smaller number to be nearest the truth; but it is difficult to speak with confidence, as an accurate census is almost unknown in eastern countries.

A religion so influential must have had its special task assigned to it by Providence, though we can only faintly guess at its nature. Its protest against many pagan errors, more especially idolatry, has been already touched upon. We may add that Islamism was probably one of the greatest checks to the progress of a much worse form of error than itself, which arose in the bosom of the church of the seventh century, namely, the species of Manichæism known as Paulicianism (*vide* Gibbon, chap. 54), which "violated the unity of God, the first article of natural and revealed religion." And it may yet possibly, as Forster and Möhler suggest, prove a preparative for Christianity in Africa, by moulding the hearts and minds of races as yet too stubborn for the mild yoke of the gospel. That He who overrules evil to good may vouchsafe such a result must surely be the devout prayer of every Christian.

Viewed externally, Mohammedanism appears to have long since reached its culminating point. In Mesopotamia, in Cyprus, in Candia, the Moslem population is not half what it was at the commencement of the eighteenth century. Persia is covered with ruins; Turkey, once the dread of Christendom, is utterly effete, and only exists through the powerful and armed intervention of France and England; Cairo has only a shadow of its once flourishing hospitals, schools, and libraries; Alexandria 15 instead of 100 mosques ever open; even Mecca itself displays ruined buildings, and the number of pilgrims is continually decreasing. (See Döllinger's concluding chapter.)

Still, however, does this creed sway the hearts of its votaries. In this respect there is as yet no clear proof of diminished power. In the present year (1857) the rising against British rule in India is most probably traceable to Moslem influence, though the Hindoo element may have combined to produce its awful and unheard-of atrocities. May that outburst prove but the prelude to its fall, and to the future triumph of Christianity. (J. G. C.)

Moham-
medanism.

Moham-
merah
||
Moir.

MOHAMMERAH, a town of Persia, about 40 miles from the mouth of the Euphrates, is situated on the left side of that river at its point of bifurcation before entering the Persian Gulf. The position of this town affords great advantages in a commercial point of view, as it communicates by means of an artificial channel with the Karun, and thereby with the fertile regions of Khuzistan to the N.E., while by the Euphrates it is connected with Basrah, Hillah, and Baghdad on the one hand, and with the sea on the other. The merchants of Mohammerah are intelligent and enterprising men; and the place will soon, it is probable, become one of the most important towns on the Euphrates. The climate, however, is excessively hot, and owing to the moist and marshy nature of the country, extremely unhealthy. A colony was founded near the site of the modern Mohammerah by Alexander the Great, under the name of Alexandria; and the adjacent district was called by him Pellæum, after his native city of Pella. This town having been destroyed by a flood, was restored by Antiochus Epiphanes, and named by him Antiochia. It was afterwards taken possession of by an Arab chief called Spasines, from whom it obtained the name of Charax Spasinu, and the district that of Characene. It was evidently at that time much nearer to the sea than at present, a circumstance which confirms the opinions of several recent travellers in this region, that the delta of the Euphrates is encroaching on the sea with unusual rapidity. Mohammerah was long an object of contention between Turkey and Persia, until it was finally ruled by a commission, instituted by the two governments in recent years, that it should adhere to Persia. During the British-Persian war of 1857 the town was bombarded and taken by the British under Sir James Outram on the 26th of March, but shortly after evacuated by them according to the treaty between the two governments signed at Paris. The frontier between the two countries, according to law, is, that the land watered by the Euphrates, excepting that about Mohammerah, should belong to Turkey, and that watered by the Karun to Persia.

MOHILEV. See **MOGHILEV.**

MOHILL, a market-town and parish of Ireland, county of Leitrim, situated at the foot of a hill, $9\frac{1}{2}$ miles E. by S. of Carrick-on-Shannon, and $92\frac{1}{2}$ miles N.W. by W. of Dublin. The town has a parish church, Roman Catholic and Methodist chapels, a dispensary, hospital, and workhouse. Some trade is carried on in corn, butter, and pigs, and numerous fairs are held. Pop. (1851) 1223.

MOIR, DAVID MACBETH, was born at Musselburgh in Mid-Lothian on the 5th of July 1798. He received his elementary education at the grammar school of his native town, and was, at the age of thirteen, apprenticed for a term of four years to Dr Stewart, a medical practitioner there. At the conclusion of his apprenticeship he completed his medical course at the University of Edinburgh, and received his diploma of surgeon in 1816. Moir had originally intended to enter the army, but the recent peace not offering much encouragement in that quarter, he returned home and spent his leisure in literary pursuits. During his laborious apprenticeship he had found time to cultivate those pursuits in which he afterwards gained a name, and had even made his first appearance as an author in some of the local magazines as early as 1812. Towards the close of the year in which he left college he put forth a small anonymous publication entitled *The Bombardment of Algiers, and other Poems*, which was not characterized either by originality or power. In 1817 the young surgeon joined Dr Brown as a partner in an extensive and laborious medical practice in the town of Musselburgh and its neighbourhood. While Moir entered upon the duties of his profession with great zeal, he nevertheless succeeded in snatching occasional moments to gratify his unquench-

able thirst for literary studies. He had already been a frequent contributor in prose and verse to the *Scots Magazine* and to Constable's *Edinburgh Magazine*, when he made his *débüt* in the pages of *Blackwood* as an occasional prose essayist, but especially as a writer of grave and comic verse. The clever effusions of *The Eve of St Jerry*, *The Auncient Waggonere*, &c., are now known to have been written by Moir, although these, as well as many others of his jocose pieces, were generally ascribed to Maginn. His serious verses bore the signature Δ, which gave origin to his literary cognomen of "Delta." This connection with *Blackwood* ceased only with his death. In 1823 Moir made the acquaintance of John Galt the novelist, who had come to reside in his neighbourhood; and so intimate did their friendship become, that when Galt was called suddenly off to America before completing his *Last of the Lairds*, the novelist commissioned Moir to write the concluding chapters of that work. *The Legend of Genevieve, with other Tales and Poems*, were collected from the various magazines in which they had originally appeared, and published, with additions, in a separate volume in 1824. This work, while generally well received by the press, met with but a very limited sale. In 1824 Moir commenced to publish in the pages of *Blackwood* his novel of *The Autobiography of Maunsie Wauch*, a work which delineated with much quaint humour and quiet power some of the most subtle peculiarities of the Scotch character, and which gained for its author very considerable reputation. Moir was warmly pressed at this time by his friends in Edinburgh to remove to the Scottish metropolis, where he had at once the prospect of a more lucrative practice and a more extensive circle of literary friends. The scenes of his early days, however, had a strong hold on the poet, and he regarded the poor among whom he had laboured so long as having peculiar claims upon him. He accordingly resolved to abide by his provincial practice, which entailed so very great drudgery, that for more than ten successive years Moir never slept a single night beyond the scene of his labours. He married in 1829, and published two years afterwards his *Outlines of the Ancient History of Medicine, being a view of the progress of the Healing Art among the Egyptians, Greeks, Romans, and Arabians*; a work which was well received by the members of his own profession. On the visitation of the cholera in 1832, Moir put forth extraordinary exertions to check the progress of that virulent and mortal disease; and as secretary of the Board of Health at Musselburgh, gave to the public his *Practical Observations on Malignant Cholera, and Proofs of the Contagion of Malignant Cholera*. These pamphlets met with great success, and were recognised, even by those who differed from them, as very masterly productions. In the autumn of 1832 Delta attended the meeting of the British Association at Oxford, and afterwards visited London, where he met Coleridge and other men of literary note. On the death of his friend Dr Macnish in 1837, Moir collected together the fugitive pieces of "the Modern Pythagorean," and published them with a Life of the author. A few years later he was called to perform a similar service to the memory of his lamented friend Galt. Early in 1843 Delta circulated privately, and then published, his *Domestic Verses*, which contained some touching pieces full of true tenderness and beauty. In the summer of 1846 he met with a severe accident by being thrown from a carriage, which confined him for months and rendered him lame for life. Moir had always taken a special interest in antiquarian studies, and on the publication of the new edition of *The Statistical Account of Scotland*, he supplied an interesting paper for that work on the antiquities of his native parish of Inveresk. In 1851 he delivered a course of six lectures at the Edinburgh Philosophical Institution, which were afterwards published, *On the Poetical Literature of the*

Moir.

||
Mola.

Past Half Century; and during the summer of the same year appeared *The Lament of Selim*.—Delta's last contribution to *Blackwood's Magazine*, a journal to which, from first to last, he had furnished no fewer than 370 articles in prose and verse. His health having given way in June 1851, he sought relief in a change of scene, and after visiting the land of Burns, he passed on to the town of Dumfries, where he died on the 6th of July of the same year.

Delta, without possessing much original power as a poet, was always fluent, generally graceful, and often singularly sweet and pathetic. He was one of the most amiable and benevolent of men, and was held in great esteem wherever he was known. A selection of his poetical works, in 2 vols., was published, with a Memoir of the author by Thomas Aird, in 1852; and a new and complete edition of his works, in 1 vol., edited by Aird, appeared in 1857.

MOISSAC, a town of France, department of Tarn-et-Garonne, is pleasantly situated on the Tarn, here crossed by a handsome bridge, in an extensive valley surrounded by hills covered with wood and vineyards, 15 miles W.N.W. of Montauban, and 97 miles S.E. of Bordeaux. The streets are narrow, crooked, steep, and ill paved, but the houses are well and substantially built. Moissac contains some remains of an ancient abbey, founded in the seventh century, consisting of cloisters, several pointed arches, and the old gateway, which is adorned with bold and fantastic sculpture. The old abbey itself, however, has disappeared, and its site is occupied by a modern edifice of no great elegance. The town contains a large flour-mill, tribunals of first instance and of commerce, and a communal college. There is a considerable trade in flour, oil, wine, linen, wool, &c. Pop. (1851) 10,655.

MOITTE, JEAN GUILLAUME, an eminent sculptor, was the son of a well-known engraver, and was born in Paris in 1747. So marked was his talent at a very early age, that the sculptor Pigalle, who was then at the head of his profession, requested to have him for a pupil. In a short time young Moitte fully justified this high opinion. His statue of "David carrying the head of Goliath" gained for him the grand prize in sculpture, and the privilege of studying at the French Academy in Rome. Accordingly he proceeded to Italy in 1768, and set himself with great enthusiasm to the study of the architectural fragments of old Rome, and the masterpieces of the great sculptors of ancient Greece. His progress was rapid, and it was then that he began to evince that correctness of design, beauty of proportion, variety of expression, and happy choice of draperies, which became so conspicuous in his subsequent works. Compelled by ill health to return to his native city in 1773, Moitte began to execute several great national works. Among these were the bas-reliefs of several of the barriers of Paris, the colossal figures representing the provinces of Bretagne and Normandy, the statue of Cassini, the bas-reliefs in the Louvre, of Moses, Numa, and the Historic Muse, and an equestrian statue in bronze of Bonaparte. About this time he was decorated by the emperor with the cross of the Legion of Honour. Moitte died in May 1810.

MOIVRE, A. DE. See DEMOIVRE.

MOKRIN, a village of Hungary, in the county of Toronthal, 42 miles W.N.W. of Temesvar. It has a Greek church; and some trade in corn, flax, hemp, cattle, sheep, and swine. Pop. about 5500.

MOLA, or MOLA DI BARI, a seaport-town of Naples, in the province of Bari, situated on a low point of land on the Adriatic, 13 miles S.E. of Bari. The town consists of an old and new portion; the former of which contains a castle, and is surrounded by walls and ditches, but is meanly built, with narrow and irregular streets. The new part of the town, however, which extends along the shore, is better laid out, and has three creeks for the accom-

modation of small vessels. The harbour is insecure; but the roadstead, though unprotected, has good anchorage. A considerable coasting trade is carried on in oil, cotton, and carrots. Pop. 8400.

MOLAI, MOLAY, or MOLÉ, JACQUES DE, the last grand-master of the Templars, was born of a noble family in Burgundy, and entered his order about 1265. In a short time his bravery against the Infidels raised him to note. He succeeded William de Beaujeau as grand-master of the Templars, and was present at the recovery of Jerusalem in 1299. Subsequent reverses compelled him in 1305 to retreat to Cyprus to recruit his forces. It was then that he was recalled to France for the alleged purpose of assisting in effecting a union between his own order and that of the Knights Hospitallers; but the real object was different. Philip the Fair, with the connivance of Pope Clement V., had resolved to fill his empty exchequer with the great wealth of the Templars, even at the cost of their complete destruction. At the same time he knew that public opinion, offended at their dissoluteness and excessive pride, would easily be reconciled to their downfall. Accordingly, after soothing down all suspicion by a series of notable favours which he bestowed on Molai, he suddenly, on the 13th of October 1307, caused the whole order throughout France to be arrested, and their effects to be seized. On the same day he took up his abode in the luxurious palace of the Temple at Paris. The Templars were tried before inquisitors on the charges of heresy and immorality. On being subjected to the torture of the rack, some chose to die rather than criminate themselves unjustly, while others confessed themselves guilty of the crimes alleged. Among the latter was the grand-master Molai. However, when brought soon afterwards before the papal commissioners, he retracted his confession, and demanded the liberty of pleading his cause before the supreme pontiff himself. But the pope had already satisfied his mind on the subject, and accordingly he abolished the order of the Temple in 1312. Meanwhile Molai was lying in prison at Paris. At length, in 1314, he was tried along with three other Templars, and as he still persisted in retracting his former confession, was condemned to be burnt alive. He protested with his last breath the innocence of himself and of his order.

MOLASSES, or MELASSES (in Portuguese *Mel de asucar* or *Melôço*, from *mellatium*, a low Latin derivative of *mel*, honey, signifying, according to Nonius, *must* concentrated to half its bulk), is the sirup or mother-water that is separated from the crystals or grains of raw sugar in the course of manufacture. It drips from those crystals like honey from the comb, a circumstance to which it no doubt owes its name, and especially to its likeness to honey in taste, consistency, general appearance, and uses. The name is sometimes given to *treacle*, which, as distinguished from molasses, is the sirup separated from the lowest boiling in refineries of sugar, or from the "bastard" sugar obtained in sugar-houses by boiling imported molasses. In France and elsewhere treacle and molasses bear indiscriminately the name *melasse*; in Germany that of *syrrup*.

Molasses varies according to the colour, strength, and treatment of the sugar which yields it. Fine bright sugar yields fine bright molasses; weak sugar, viscid or weak molasses. Muscovado or unclayed sugar yields thick or heavy molasses; clayed sugar thin, but, when kept from becoming acid, strong molasses. By strong molasses is meant molasses capable of producing a large per-centage of granulated sugar. The heaviest molasses, though containing less water, and therefore a greater per-centage of saccharine matter, is not generally the strongest, its thickness being often connected with the presence of much grape-sugar and impurities. The best molasses is obtained in the earlier periods of the crop season, and before rains set in.

Molasses is usually of a dark-brown colour. St Croix,

Molai
||
Molasses.

Molasses. Barbadoes, and Porto Rico, produce the finest, of that yellow or amber colour which is preferred. The progress of improvement in the making of sugar, for which there is still ample scope, may be expected to improve the colour, as well as reduce the proportion yielded, of this the less profitable extract from cane-juice.

Molasses is shipped in tight casks (called in this country *puncheons*; in Cuba and America, *hogsheads*), containing from 9 to 15 cwt. each. The bungs are left out to give free vent to the fermentation to which it, particularly if strong and fresh, is subject on the voyage. Iron tanks have been used, but only to a very limited extent. The deposit of sugar which frequently settles at the bottom of the casks during the voyage is called *foot*.

Although molasses is produced wherever sugar is made, the only parts of the world which export it in any considerable quantity are the West India Islands, of which Cuba alone in 1856 contributed 226,000 casks, mostly of large size, or two-thirds of the whole commerce in the article. Brazil, Mauritius, the British East Indies, Java, and the Philippines, which collectively supply about a third of the world's sugar, do not ship any quantity worth notice; yet they might do so profitably, notwithstanding length of voyage, if better means were devised to prevent waste and acidity.

Much molasses is converted into *rum* on the estates. Jamaica distils all its molasses. A great deal of what is sent to the United States of America, and (when grain is dear, or inferior molasses, chiefly clayed from Cuba, is cheap) some also of what is sent to the United Kingdom, finds its way to the distilleries, producing from $6\frac{1}{2}$ to 7 or 8 gallons of proof spirits per cwt., unexceptionable in quality. Sugar is supposed to yield 11 to $11\frac{1}{2}$ gallons per cwt. In the city of Boston alone, the chief seat of this branch of the trade, the quantity distilled was, for the years 1854-5-6, near 50,000 casks a year. The returns for the United Kingdom show 134,682 cwts. so used in 1856.

The laws of the United Kingdom prohibit the use of molasses in breweries, in order to maintain the duty on malt at its present high rate. For domestic brewing this material is allowed and is suitable, but it is not so used. There are several other ways in which it might be serviceable, but it is not used, because it is not sold here in retail; common treacle, which has a better consistency, and is also cheaper, or refiners' "golden sirup" (a finer sort of treacle), being kept by the grocers in preference. In the United States and British America molasses is largely used as an article of diet in its natural state. Molasses or treacle from beet-root sugar, an extract necessarily obtained in large quantities in the beet sugar-works of Europe, has an unpleasant vegetable flavour, and is employed for feeding cattle and for making alcohol and acetic acid.

The principal consumers in the United Kingdom are the refiners of Greenock, Liverpool, London, and Leith, who, by operations not yet benefited by modern science so much as may be hoped for, obtain from it a dark, or, as the case may be, a yellow sugar, resembling West India muscovado, the residue being treacle. Of 82,000 casks imported into the United Kingdom in 1856, half came to the seaports of Clyde, 25,000 to Liverpool, and 15,000 to London.

The magnitude of the molasses trade is further shown by the following figures:—The United States imported in each of the years 1854-5-6 above 25,000,000 gallons, or about 2,500,000 cwt., besides consuming its own growth, which in these years amounted to not much less. In the same years this kingdom imported an average quantity of 950,000 cwts. The remarkable progress of this trade is shown by comparing the imports into the kingdom in the years 1820-30-40, when they were only 39,991, 250,648, and 432,220 cwts. The increase is due to the greater indifference with which the planters regard the making of rum, to the enlargement of the sugar-boiling business in the

chief northern ports of Britain, to the removal of the prohibitory duty, and to the vast extension of the growth of the cane, especially in the highly prosperous slave-labour Spanish colony of Cuba. It is worthy of notice that this "sweet" is used almost exclusively by the English-speaking countries of the world,—Great Britain, and the states and colonies to which she has given birth.

The present duty on molasses is 5s. per cwt., and the price, exclusive of duty, has ranged for some years between 7s. and 20s. per cwt., or about half the price in bond of the lowest sorts of sugar. In this country it is sold by weight; in the United States and the colonies by measure (the old gallon). An imperial gallon weighs from 13 to 14 lb. The specific gravity of molasses from muscovado sugar is about 1.370, and from clayed sugar 1.356.

A trade has lately arisen between Cuba and the United States in *melado*, which is cane-juice concentrated, or sugar with the molasses remaining unseparated from the crystallized portion. (See SUGAR.) (R. A. M.)

MOLD, a parliamentary borough and market-town of Wales, county of Flint, pleasantly situated in a fertile valley near the right bank of the Alen, 13 miles W. from Chester. The town is irregularly built, chiefly of brick. The principal buildings are,—the parish church, a large and handsome edifice of the fifteenth century, with an embattled tower, richly carved; and the county-hall, a fine building, which cost L.3000. There are also places of worship belonging to the Methodists, Independents, and Baptists; national and other schools; a market-house, and a savings-bank. The parish contains extensive coal pits, and mines of lead and iron, as well as some manufactories of earthenware, bricks, and cotton. Bailey Hill, a little to the N. of the town, was in the twelfth and thirteenth centuries crowned by a fortress, which was the scene of many sanguinary fights between the English and Welsh during the border warfare. It was captured by the latter under Owen Gwynedd in 1145, was retaken by the English some time after, but again came into the hands of the Welsh in 1201. In its churchyard is the humble grave of Richard Wilson, the celebrated landscape-painter. Mold combines with Caergwyle, Caerwys, Flint, Holywell, Overton, Rhuddlan, and St Asaph, in returning a member to Parliament. Pop. (1851) 3432.

MOLDAU, a river of Bohemia, rising in the Bohemian Forest, on the frontiers of Bavaria, and flowing in a S.E. direction as far as Rosenberg. It then turns to the N., and continues generally in this direction till it joins the Elbe at Melnik, after a course of 230 miles. The most important tributaries of the Moldau are the Luschnitz and the Szava on the right, and the Wattava and the Beraun on the left. The principal towns on its banks are Rosenberg, Budweis, and Prague. In the lower part of its course the Moldau is a large river, and contributes more water to the Elbe than the Upper Elbe itself. It abounds in fish, and is navigable to Prague for vessels of 60 tons, to Budweis for barges of 10 or 15 tons, and to Rosenberg for smaller craft.

MOLDAVIA, one of the two Danubian Principalities under the sovereignty of Turkey, is bounded on the N. and E. by the Russian province of Bessarabia and the Black Sea, S. by the principality of Wallachia, along with the Danube and the Kilia branch of that river, which separate it from Turkey, and W. by the Austrian provinces of Transylvania and Bukowina; lying between N. Lat. 45. 15. and 48. 13., and E. Long. 25. 10. and 30. 13. It has a length of about 200 miles from N. to S., an average breadth of about 100, and contains an area of about 19,932 square miles. The Carpathians form the natural boundary on the W., and separate it from Transylvania. These mountains rise to the height of from 3000 to 5000 feet above the sea, and send off numerous branches to the eastward, gradually diminishing in height as they approach the banks of

Mold
||
Moldavia

Moldavia. the Sereth, which traverses the country from N. to S. The general surface of the country, excepting the part occupied by the marsh-lands at the mouth of the Danube, slopes from W. to E., and terminates in an undulating plain of considerable extent. The principal rivers of Moldavia are the Sereth and the Pruth; the former rises among the highlands of Bukowina, flows first E. and then S., and finally falls into the Danube after a course of about 270 miles. The Pruth rises in the same region as the Sereth, flows S.S.E., and falls into the Danube at Reni after a meandering course of 360 miles. It forms the north-eastern boundary of Moldavia, and is navigable for three-fourths of its length. The other important rivers are the Bistritz, Birlat, Moldava, Tatros, and Tazlen, all of which flow southward, and fall into the Sereth. The soil of the country is rather stony in the E., but gradually improves in fertility as it approaches the rivers; and the greater part is abundantly productive, amply rewarding the labour which is applied to it, notwithstanding the excessive heat of the summers, and the intense cold of the winters. The corn is excellent, especially the summer or hard wheat. The wine is good, and produced in abundance. Excellent cattle are fattened in the meadows; and good flax, hemp, honey, wax, and all kinds of fruits, are most abundant. The mineral resources of Moldavia are very great; but little advantage is taken of their abundance. Rock-salt, saltpetre, and bitumen, are the principal minerals, and these are found chiefly in the Carpathian Mountains and towards the N. of the principality; while small quantities of gold-dust have been obtained from some of the rivers. Great numbers of horses, cattle, sheep, goats, and hogs are reared in the meadows and forests of Moldavia; and some of the boyars or noblemen have studs of no fewer than 400 or 600 mares. The climate of Moldavia is exposed to severe cold in winter and excessive heat during summer. Rain falls in large quantities in the months of June and September; but the weather in October and November is very mild. The vicinity of the marshes which occupy that section of the state between the Pruth and the Black Sea is, however, very unhealthy, especially during the hot season. The inhabitants live in a wretched manner in earthen huts, without windows or chimneys, and sometimes underground. The manufactures are few and rude in kind. But this want is fully compensated by the great advantages for importation and exportation afforded by the Danube, now open to all nations.

The three ports of Moldavia are Galatz, Ismail, and Reni, all on the Danube; but the first is by far the most important. In the year 1855, when the operations of the Russo-Turkish war were transferred from the Danube to the Crimea, and the trade of that river was thus enabled to resume its usual importance, the number of shipping and tonnage entering and clearing at Galatz amounted to a total of 1698 vessels, with 417,584 of aggregate tonnage. The following table shows the value of the imports and exports of Galatz from and to the various countries in 1855, as well as the amount and value of the chief articles imported and exported during the same year:—

Value of Imports from—			Value of Exports to—		
Britain	L.253,240		Greece.....	L.668,920

Moldavia. The population of Moldavia is almost identical in kind with that of the neighbouring principality of Wallachia, and seems to belong to the same race as the ancient Dacians, who inhabited this region from the earliest times. The Moldavians, indeed, differ very little from their ancestors in appearance, costume, and manner of life, and they still bear the name of Roumuni or Romans, while their dialect is a corruption of Latin with Slavonic, Turkish, and Tartar words. There are four classes of people in Moldavia, viz.:—1. The boyars or nobility, and the clergy, who are exempted from taxation; 2. The privileged classes, such as the academic corporation at Jassy, but who are liable to taxation; 3. The villagers; and 4. The gypsies, who have no civil rights, and, till a recent period, were in a state of slavery either to the government or to private individuals. They have now, however, been released from servitude; those belonging to the government having been emancipated several years earlier than the slaves of the nobles, who received their liberty only in 1853. The established religion of Moldavia is that of the Greek church, superintended by a metropolitan and a vicar. The capital is Jassy; and the principality is divided into Upper and Lower Moldavia, and subdivided into districts, of which the former contains six, and the latter eight, as follows:—

Upper Moldavia.

Districts.	Chief Towns.	Pop. (1850).

The principality of Moldavia occupies part of the region known in ancient times by the name of DACIA (which see). In the later times of the Byzantine Empire it was overrun by several barbarous tribes, and the inhabitants were driven across the Carpathian Mountains, where they remained until the thirteenth century, when a small colony, under a chieftain called Bogdan, re-established themselves in their country, which received from their leader the name of Bogdania, by which it is still known among the Turks and natives. This prince and his son gradually extended their power over the whole of Moldavia. The princes of Moldavia were at that time called *voyvodes*, or military leaders; a name which was afterwards changed by the Turks to that of *hospodars*, which is still retained. In the thirteenth century Moldavia was frequently disturbed by civil war, occasioned by rival claimants for the crown, and these dissensions rose to such a height that the country was divided into two parts, one of which acknowledged the sovereignty of Poland, and the other that of Hungary. A union was, however, soon after effected, and Moldavia became subject to Hungary, paying at the same time a tribute to the Poles. In 1536 Moldavia came under the protection of the Sultan. For a considerable time after this period it was the scene of constant wars between the Poles and Turks, until the claims of the former to the sovereignty of the state were finally abandoned in 1621, and peace concluded between Turkey and Poland. But notwithstanding the authority of the Sultan was now unquestioned, the boyars still continued to elect their own voyvodes, a proceeding which caused numerous disputes between them and the

Moldavia. *Porte.* In 1710 Demetrius II., voyvode of Moldavia, entered into negotiations with Peter the Great of Russia, by which the latter undertook to force the Turks to restore the principality to its former independence. On the failure of the Russian attempts, and the retreat of Peter, who was accompanied by Demetrius, the Sultan deprived the Moldavians altogether of the privilege of electing their princes. These were thenceforth nominated by the *Porte* direct, and received their modern title of *hospodars*. In 1738, during the war of Austria and Russia against Turkey, Moldavia was invaded by a Russian force under Münnich, and occupied for two years, but was evacuated after the peace of Belgrade. In 1769 it was again occupied by the Russians, and in consequence of the victories gained by them over the Turks, became for a short time subject to the Czar. It was, however, restored to Turkey by the peace of Kutchuk Kainaryi in 1774. Three years later, Bukowina, which had before formed a part of Moldavia, was ceded to Austria. In 1789 this unfortunate principality was again the scene of contest between Russia and Turkey, until the peace of Jassy in 1792, when the Russian frontier was fixed by the Dniester. In the war of 1807-12 Moldavia again fell into the hands of the Russians, who, by the treaty of Bucharest, acquired possession of Bessarabia, and thus extended their frontier to the Pruth. At the commencement of the Greek war in 1820 an insurrection broke out in the Danubian Principalities, but was suppressed by the Turks, who then occupied with an army the two principalities until the year 1826. It was then agreed by an article in the treaty of Ackermann, that the hospodars of Moldavia should be elected by the boyars out of their own number for a period of seven years. In 1828 another war between Turkey and Russia broke out; and Moldavia was occupied by the Russians without opposition until peace was established by the treaty of Adrianople in 1829. By this treaty it was stipulated that all the Turks should leave Moldavia, which was thenceforth to be under the protection of Russia. The hospodars were now to be elected for life, and their power was limited by a *divan*, consisting of ten boyars, and an assembly of deputies from the boyars, the clergy, the academic corporation, and the landowners, which was to meet annually. An annual tribute is paid to the *Porte* of three millions of piastres, or somewhat more than L.27,000, and an additional tribute is paid at the accession of each new hospodar. The Moldavians were also bound to pay to the *Porte* a yearly sum as a compensation for the surrender by the latter of the fortifications N. of the Danube, and of the rights they formerly possessed. The principality was governed by the Russian general Kisseleff from 1832 to 1834, when the constitution was approved by the *Porte*; and in the same year Michel Stourdza was elected hospodar. A conspiracy was formed in 1840 to unite the principalities of Moldavia and Wallachia into one state, but without success. In 1848 the influence of revolutionary sentiments was felt in Moldavia; the people of Jassy demanded a new constitution, and, although the hospodar successfully resisted this movement, he laid down his authority in the same year. In 1849 the treaty of Balta Liman was concluded between Russia and Turkey, in accordance with which the hospodars were to be nominated by the Russian and Turkish courts for a period of seven years; and in June of that year Gregory Ghika was appointed hospodar. In 1853 a Russian army entered and seized possession of Moldavia and Wallachia, and the hospodars of the Principalities retired. After attempting in vain to cross the Danube in Wallachia, the Russians, in the spring of 1854 crossed that river at Galatz, and seized the fortresses in the Dobrudscha. They then proceeded to lay siege to Silistria, but this town was so vigorously defended that they were obliged to raise the siege, and the British and French troops having arrived at Varna, the Russian army

evacuated the Principalities in the autumn of 1854. The hospodars then returned to their respective governments, and the Principalities were occupied by an Austrian army. At the conference of Vienna in March 1855 a proposal was made by Baron Bourqueney, the French plenipotentiary, to unite the two principalities under a foreign prince, subject to the sovereignty of Turkey; but the discussion of this proposal was deferred until the opinion of the *Porte* was known. By the treaty of Paris in 1856, a portion of Bessarabia was reunited to Moldavia, so that the Russian territory had no longer any communication with the Danube. At the same time the protectorate of Russia over the Principalities was abolished, and the continuance of all their rights and immunities was guaranteed by the European powers. The future organization of the Principalities was to be decided according to the wishes of the majority of the people. The treaty of Balta Liman, in accordance with which the hospodar Gregory Ghika governed Moldavia, being annulled, and at the same time the term of seven years for which he was appointed having expired, that prince laid down his authority, and the Sultan appointed Theodore Baltche hospodar in his stead. During his reign Ghika had granted to the Moldavians the liberty of the press, and had shown himself favourable to the union of the Principalities, which was the wish of the majority of the people; but the present hospodar, as well as the Sultan, is opposed to it, and the liberty of the press has been suppressed by the Sultan. The receipts of the principality in 1853 amounted to 13,235,230 piastres or L.129,411, and the expenses to 12,456,324 piastres or L.122,320, of which the tribute to the Sultan made up 715,000 piastres or L.65,000. The army of Moldavia in the same year consisted of a force of 15,944 men. (For the more recent history, see WALLACHIA.)

MOLESWORTH, SIR WILLIAM, an eminent British statesman, was the lineal descendant of an old Cornish family of extensive landed property, and was born in London in 1810. In his thirteenth year he lost his father, and succeeded to the family estate and baronetcy. He studied at Cambridge, but was rusticated there for challenging his tutor to mortal combat. After spending some time at the university of Edinburgh, engaged in the study of mathematics, classics, and metaphysics, he repaired to Germany. There his attention was chiefly devoted to philology and history. He then made the usual tour of Europe, and returned to England in 1831. In the same year, before he had attained his majority, he delivered an earnest and elaborate speech in favour of parliamentary reform at a Cornish county meeting. This first appearance of his in public prepossessed the local Liberals so much in his favour, that in 1832 he was returned without opposition as one of the members of Parliament for the eastern division of Cornwall. He was re-elected by his constituents in 1835; but in 1837 so powerful had the reaction against his opinions become, that he despaired of regaining his seat. He therefore became a candidate for Leeds, and was successful. On the dissolution of 1841, the clouded prospects of his party deprived him of all hope of being returned by his former constituency, and induced him to retire without a contest from parliamentary life. Sir William Molesworth devoted the next four years to a close study of politics and social economy. In 1845 he was again on the field as a candidate for Southwark. His bold advocacy of the Maynooth grant excited formidable opposition; but his open and conscientious conduct at length won the day, and he continued to represent this constituency during the rest of his life. Ever since his entrance into Parliament Sir William Molesworth had been gradually acquiring the reputation of a clear, sound, logical, and weighty speaker. He had directed all his energies to the reformation of the colonial office, had aroused the attention of Parliament to that subject, had

Molesworth.

Molière.

explained with great ability the principles of colonial self-government, and had finally convinced statesmen and the public of the truth of his views. It was therefore with general approbation that he was appointed First Commissioner of Public Works in January 1853, and Colonial Secretary in July 1855. But this latter office he did not long enjoy. He died of a low gastric fever in October 1855.

MOLFETTA, a walled seaport town of Naples, province of Terra di Bari, on the Adriatic, 16 miles W.N.W. of Bari. The town as approached from the sea has a fine appearance, many of the houses being handsomely built of a white stone resembling marble, but its streets are narrow and dirty. The principal buildings are,—a cathedral, several churches, a college, and a castle. The chief manufactures are linen goods and saltpetre. Some ship-building is also carried on. The harbour is formed by a mole and a sandbank, which acts as a breakwater, and is well sheltered, except from the N. wind. A considerable trade is carried on in corn, oil, almonds, and other articles. In the neighbourhood of the town there are some curious oval caves, arranged in tiers, and hewn out of a limestone rock. In all these saltpetre is found; and one of them, called the Nitre Cavern, is 1400 feet in circumference and 112 in depth. Pop. 17,000.

MOLIÈRE, the assumed name of JEAN BAPTISTE POQUELIN, who was born at Paris on the 15th of January 1622. His father, Jean Poquelin, exercised the vocation of *tapisier*, and subsequently that of *tapisier valet-de-chambre* to Louis XIII. Young Poquelin, who seems to have been designed for the same trade, received originally a somewhat meagre education, and remained connected with his father's shop till he was fourteen years of age. Nothing is known respecting the boyhood of Molière till the year 1637, when his father succeeded in securing the reversion of his office for his eldest son Jean Baptiste, then in his fifteenth year. It has been customary to fill up this long blank in the early life of the great dramatist by an apocryphal story of a fond grandsire extorting occasional permission to take young Poquelin to witness the theatrical performances at the Hôtel de Bourgogne. Unfortunately, however, it turns out, on more accurate inquiry, that this benevolent old gentleman died just four years after his grandson's birth. Whether or not the slumbering genius of Molière was awakened by the indifferent specimens of the histrionic art which he beheld at the Hôtel de Bourgogne, it is at least certain that in the year 1637 he became a student at the college of Clermont, now known as that of Louis le Grand. During his five years' residence at this institution he enjoyed the private instruction of Gassendi, one of the first philosophers of his age, and numbered among his fellow-students such men as Chapelle, Bernier, Cyrano de Bergerac, Hesnaut, and Condé's brother, the Prince de Conti, afterwards known as the liberal patron of letters and the friend of Molière. His relation to Gassendi, however, is the principal matter of interest at this period. The influence exerted over the expanding genius of the future dramatist by the teaching of this illustrious man must have been at once powerful and abiding; and in the withering scorn and fearless satire with which Molière afterwards assailed the vices, and unmasked the hypocrisy of his age, one can detect the hand of a man who in his early years was a favourite pupil of a philosopher who made bold to challenge the authority of Aristotle, and to enter the lists with Descartes. If Molière distinguished himself in philosophy at the college of Clermont, he gained a name for classical learning hardly less eminent. It was here he attained to that intimate acquaintance with the Latin dramatists which he afterwards turned to so good account in his compositions for the stage.

On the completion of his collegiate course, Molière commenced the study of law, which he prosecuted with more or less regularity during the three following years. It is dif-

ficult to say whether or not Molière had resolved upon any definite plan of life previous to this time; at all events, a circumstance occurred just when he had reached his twenty-third year which proved the turning-point in his history. It so happened that one Madeleine Béjart, a provincial actress of some celebrity, visited Paris in 1645, when "a young fellow named Molière," as old Tallemant des Réaux drily informs us, finding greater attractions in this interesting lady than he had yet discovered in the dull pages of Cujas and Trebonian, renounced his legal studies, followed the charmer to the provinces, and subsequently joined her *troupe*. Thus it was that Jean Baptiste Poquelin, or as he now called himself Molière, was led, whatever may have been his previous leanings, to assume a profession which from that hour became the business of his life. During the year which inaugurated his dramatic career Molière endeavoured to establish himself at Paris in connection with the *Théâtre Illustre*, which had been originated by a society of young men of good family, who considered themselves possessed of a talent for declamation. Failing in this attempt, Molière betook himself to the provinces, and soon found himself a member of the same company with the previous object of his admiration, Madeleine Béjart. Little is known respecting his provincial life, which occupies a space of not less than twelve years (1646–1658), except what is exceedingly meagre and fragmentary. During the greater part of that time Molière was the chief of a company of strolling players who spent their time in amusing the citizens of Nantes, Vienne, Bordeaux, Lyons, Pézenas, Béziers, Grenoble, and Rouen. From the outset Molière resolved to combine the profession of actor and author, and endeavour, while he built up his fame, to secure his fortune. He accordingly assumed the function of author by converting certain Italian pieces into acting plays for his company, and which were characterized more by the faults of the Italian theatre than by the genius of Molière. His first regular production was the *Etourdi*, a comedy in five acts, which was represented at Lyons in 1653, where it met with so much success that the principal performers belonging to another *troupe* permanently attached themselves to the fortunes of Molière. His play, although it surpassed the comedies of Scarron and Scudéri, which preceded it, was nevertheless much inferior to Molière's subsequent productions. It is made up of a number of isolated incidents and intrigues, which succeed each other certainly, but display very little inherent connection. Yet, amid all these defects, it gave marked evidence, in its spirited dialogue, ready repartee, and felicitous flow of language, of very decided advancement in stage composition. This piece was afterwards "revised and polished" by Dryden into his *Sir Martin Marfall*. (See Downes's *Roscius Anglicanus*, p. 38, 1789.) Reinforced by the recent valuable accession to his company, Molière repaired to Béziers, where his former class-fellow, the Prince de Conti, was holding the states of Languedoc. Here the rising player received the distinguished patronage of his noble friend, and his company was called upon to put forth all their energies to furnish entertainment to the prince, the assembly, and the city. The *Depit Amoureux* was acted here for the first time in 1656. As a whole, it is inferior to the *Etourdi*; yet it met with decided success. So greatly was the prince delighted with the genius of the dramatist, that it is said he offered to make him his secretary,—a distinction which Molière respectfully declined, remarking, "I am a tolerable author, but I should make a very bad secretary." Fortunately for the glory of the French drama, Molière had the courage to be faithful to his genius, a resolution which did as much honour to the player as the handsome offer did to the prince.

Having continued for some time his strolling performances in the south of France, Molière approached the capital, attracted by the hope of better fortune and greater

Molière.

Molière. fame. After assiduous efforts he succeeded, through the influence of De Conti, in obtaining permission to give a theatrical entertainment before their majesties and the court. This was a trying position for the strolling player, but he trusted to his genius, and it proved all-sufficient. Accordingly, on the 24th day of October 1658, his company played Corneille's tragedy of *Nicomede* before this august assemblage, at a theatre erected at the guard-hall of the old Louvre. Molière, who felt that his company was inferior in tragedy to the *troupe royale* of the Hôtel de Bourgogne, who were present, came forward after the performance, and adroitly observed that he and his actors were but feeble copies of those first-rate models, and hoped that his majesty, who had graciously tolerated their rustic ways, would allow them to play one of the little comic pieces which had gained their author some reputation in the provinces. The king granted the request, and the adventurous provincials represented a one-act farce, now lost, called the *Docteur Amoureux*, with so much success that they were desired by royalty to remain at Paris, and received permission to assume the title of *Troupe de Monsieur*, the king's brother, and to play alternately with the Italian comedians at the Petit-Bourbon Theatre. So this author-actor, with his squat, ungainly figure, coarse features, and melancholy countenance, finds that his reception by the fastidious public of Paris has not been inferior to that given him by the provinces. There was a fascination in Molière's person despite all its natural defects. Every limb and muscle of that awkward figure had something to say for itself; and, as a contemporary remarked of him, "he is an actor every inch of him, from the crown of his head to the soles of his feet." How he entertained the public at the Petit-Bourbon during the succeeding year is not known. It is certain, however, that he produced his celebrated *Précieuses Ridicules* in November 1659, which had such an extraordinary success that, though the prices of admission were trebled on the second day, the piece had a run of four months. The fame of Molière and genuine French comedy began alike with this play. Its author was hailed enthusiastically from the parterre with "*Courage! courage! Molière, voilà la vraie comédie.*" If not designed as a satire upon all the ladies or *précieuses* connected with the famous Hôtel de Rambouillet, a literary circle which could boast of some of the most eminent men of the age as its supporters, this play was certainly meant to heap ridicule upon that class of *précieuses* who perverted alike good taste and correct feeling by the elaborate affectation of their talk, and the mock refinement of their sentiments. The characters and manners of this class were portrayed with extraordinary power and boldness; and it was with no small consternation that these absurd coteries found themselves thus ruthlessly impaled before the public by this comic censor, who kept all Paris laughing at their follies for four months in succession. The public now saw what was in store for them when Molière chose, as he modestly phrased it, "*étudier le monde.*" His next piece, *Sganarelle, ou le Cocu Imaginaire*, was given to the public on the 28th of May 1660, and met with a success more than equal to its merits, having been acted forty times in succession.

The beginning of 1661 found Molière installed in his new theatre, the *Salle du Palais Royale*. Whether or not it was owing to the associations connected with the past history of this place that Molière felt induced to appear as a tragic author, he at all events produced a heroic comedy termed *Don Garcie de Navarre; ou le Prince Jaloux*, in 1661, imitated from the Italian, which proved an utter failure, and was the source of loud jubilation to his enemies. Molière withdrew it, and afterwards transferred some of its lines to the *Misanthrope*. On the 24th June 1661 he made another attempt, in his *École de Maris*, to retrieve his fallen reputation, and met with the most brilliant success. He owed the fundamental idea of this piece to

Terence in his *Adelphi*, and some of the details he borrowed from Boccaccio and Lopez de Vega. During the same year he was engaged by the unfortunate Fouquet to compose a comedy for the celebrated fête which the superintendent of finance gave to Louis XIV. at Vaux, a few days before that monarch arrested and imprisoned for life the minister who entertained him. Molière had only five days to execute his task, and at the end of that time he produced *Les Fâcheux*, a piece which introduces us to the most provoking set of "bores" that ever afflicted mortal. The materials are of the slenderest, having been designed to be acted during the intervals of a ballet; but such a lecture on the follies of character and manners as it contains Molière alone could read. An event occurred on the 20th of February 1662, just two days after the appearance of *Les Fâcheux*, which was not destined to increase the happiness of the dramatist. He became united to Armande Béjart, a sister of that Madeleine Béjart, with whose charms the young lawyer Jean Baptiste Poquelin had been smitten some twenty years before. The envenomed tongue of slander laboured industriously to circulate the calumny that Molière's wife was the daughter of his former mistress; and the *chef* of the Hôtel de Bourgogne kindly improved upon the scandal by submitting to the king that Molière's death would leave his wife at once fatherless and a widow. His majesty, however, showed his appreciation of these malicious reports by condescending, in February 1664, together with Henrietta of England, Duchess of Orleans, to be the sponsors of Molière's child. Much of the loathsome scandal regarding this affair has been swept away by the unequivocal testimony of certain legal documents which had escaped detection till 1821. But the worst trial of all awaited the much-wronged dramatist, in the imprudent coquetry of his wife, which served not a little to embitter the remainder of his domestic life. He pursued his labours, however, with unmitigated ardour, although he had by this time drawn down upon himself a host of assailants. The parties whose ridiculous conceits and absurd follies he had so ruthlessly exposed, too wise to express the rankling pain which the arrows of the censor had inflicted, now set themselves up as guardians of the purity of the national morals and of the national language. His next three plays aggravated the animosity of his enemies a hundred-fold. The *École des Femmes* appeared on the 26th December 1662; the *Critique de l'École des Femmes*, an energetic defence of the former, on the 5th January 1663; and the *Impromptu de Versailles* in October 1663. In the first of these he was accused by the pseudo-religious party of Paris of turning religion into burlesque,—a class which he drove almost frantic by sending home the satire with tenfold force and power in his *Critique*. Nor did his *Impromptu* tend to conciliate his enemies. On the contrary, the cutting and merciless exposure which it contained of the envious rivals whom his genius had eclipsed, drew down upon him the *troupe* of the Hôtel de Bourgogne like a nest of hornets. His next piece, *La Princesse d'Élide*, executed at a signal from the king, who stood constantly by him, was composed in haste to garnish a splendid fête of Louis at Versailles in May 1664; and while it afforded little scope for Molière's comic powers, belonging as it did to the gorgeous and romantic drama, it nevertheless was received with great applause. It also appears that the first three acts, or rough sketch, of the celebrated *Tartuffe* were presented on the sixth day of the entertainment, and the piece was regarded by the king as "fort divertissante;" yet he saw reason to forbid its public representation. Molière's next production of the same year was *Le Mariage Forcé*, a one-act comedy, with a bold and simple plot, but full of inimitable wit and ridicule, chiefly directed against the sophists of the Sorbonne. In the *Festin de Pierre*, which came out in 1665, Molière de-

Molière.

Molière. pictured with extraordinary satirical power the character of an incorrigible hypocrite and libertine in Don Juan, borrowed from a Spanish story, which has furnished material for the creative genius of Molina, Mozart, and Byron. Some critics of this work went so far as to invoke the spiritual censure and the doom of the civil magistrate on the author; but the king supported him, and not only allowed his company to assume the title of *Troupe du Roi*, but also bestowed upon them a pension of seven thousand livres, in addition to the thousand livres (L.40) previously granted Molière as a crown pension. *L'Amour Médecin*, which appeared at the royal command in September 1665, was produced in five days, and was a declaration of war against a new and influential body of enemies. In this piece he directed his polished satire against the quackery and pedantry then prevalent among the medical faculty of Paris. After the lapse of nine months, an unusual term of repose for Molière's muse, caused partly by his own illness and partly by the death of the queen-mother, the 4th of June 1666 brought a day to be remembered in the annals of the drama. It was then that the *Misanthrope* was first acted at the Palais Royal. This piece is universally accounted by French critics as the most correct in point of style of all Molière's compositions, and not a few regard it as his *chef d'œuvre*. It was in this play he introduced the passage from a translation of Lucretius which he is said to have executed and afterwards committed to the flames. It was received but coldly at first by the Parisian public, and its author was compelled to heighten its attractiveness by attaching to its representation the lively farce of *La Médecin Malgré lui*, founded on an old *fabliau*, and afterwards translated into English by the celebrated novelist Henry Fielding, under the title of *The Mock Doctor*.

Passing over *Melicerte*, the *Pastorale Comique*, and *Le Sicilien*, which appeared about this time at St Germain, as slim in material and rather dull in detail, we come to the most remarkable of all Molière's performances. Hitherto it had been more the aim of his satire to chastise folly than to unmask and brand vice. Three years before we saw the rude outline of the *Tartuffe* sketched at Versailles. Scruples as to the probable reception of the piece induced the king to interdict its representation. Alterations were made in the play at the desire of royalty, and Molière used all his efforts to tone down the colouring, and remove any semblance of personal allusion. On the departure of Le Grand Monarque to pursue his conquests in Flanders, permission was obtained by Molière to represent this long suppressed *Tartuffe* at the Palais Royal. This piece accordingly made its appearance on the 5th of August 1667, and produced a most extraordinary sensation. In the depth and power of its composition it was felt to outstrip all previous attempts at comedy which France had known. It was received with the most triumphant and deafening applause; and yet twenty-four hours did not elapse before the *premier président* interdicted a second representation, and the archbishop had exhausted his thunders of excommunication by the week's end against all who should act, read, or listen to, in public or private, the said comedy of *Tartuffe*. The Jesuits at first supposed it was a satire upon the austerity of the obnoxious Jansenists; while the latter sought their revenge in giving currency to the notion that *Le Tartuffe* was but a postscript to the *Provinciales* of Pascal. The truth is, it was not religion of any form which Molière ridiculed; it was the insincere professors of religion. Where religion is in a healthy state, the exposure, of the vice of hypocrisy will always be hailed with applause rather than received with censure. Satire, although a dangerous weapon, is, when employed in good faith and honest purpose, often the only effective means of assailing a crime equally odious in the sight of God and man. Such thorough-paced hypocrites are not to be moved by ordinary means; they "are

touched and shamed by ridicule alone." Yet Molière's purpose, as is too often the case, was doomed to be misunderstood; and even such men as Bossuet and Bourdaloue, fearing lest the keen blade which smote down so mercilessly the subtle hypocrite, might glance back and wound the simple, joined with not a little intemperance in the hue and cry raised against the audacious moral censor. Molière, however, fearlessly held on his way; and if the intrigues and petulance of a so-called religious faction influenced his royal patron to confirm the interdict, Molière lived to have his revenge. The fame of the *Tartuffe* soon found its way across the Channel, and by the industry and taste of the unfortunate actor Matthew Medburn, the play-goers of the British metropolis learned early to applaud the genius and admire the courage of this indomitable French comedian. (See the *Roscus Anglicanus*, p. 27.) Clamour and controversy were still raging when the *Amphitryon*, a questionable drama taken from Plautus, came out with its inexhaustible stock of keen wit and inimitable humour. Voltaire tells us, the first time he read it he tumbled off his chair, convulsed with laughter, and nearly broke his neck! This play, together with *George Dandin* and *L'Avare*, appeared during 1668. *George Dandin* was a successful exposure of the mischief done by unequal marriages, especially by the union of impoverished aristocrats with wealthy *parvenus*. The general conception of *L'Avare* was taken from Plautus, but adapted to modern society with a degree of truth and felicity which none but a Molière could command. The delineation of the miser, although one of the author's most successful attempts, was less favourably received than usual, owing, it is said, to its being written in prose. It has since, however, received ample justice. The highest compliment paid to the truth of the piece was by a miser himself, who was, it is said, so pleased with the excellent lessons of economy which it contained, that he actually paid the cost of admission to witness the performance. This play was transferred to the British stage, as *The Miser*, by Henry Fielding. Since the proscription of *Le Tartuffe*, Molière had been urgent in his endeavours to obtain for it a fair hearing. After repeated opposition and discouragement, his efforts were crowned with success, and the *Troupe du Roi* performed on the 5th February 1669 *Le Tartuffe*, ou *l'Imposteur*, to the great horror of the bigots, who ceased not to invoke the nether fires to consume the wicked dramatist. Passing over the clever farce of *Monsieur de Pourceugnac* (1669), and the satire on astrology of *Les Amants Magnifiques* (1670), we come to a masterpiece of comic art in *Le Bourgeois Gentilhomme*, first presented before the court at Chambord on 14th October 1670. This play, though defective in construction, continues to be one of the most popular of Molière's compositions. It exposes in an exceedingly amusing manner the ridiculous absurdities into which a man is led who would force his way into a higher sphere than his own, with no other qualification but the weight of his purse. In this relation the ignorant pomposity of Monsieur Jourdain, and the pretentious pedantry of his fashionable instructors, will continue to afford matter for genuine laughter as long as the piece is known. The *Fourberies de Scapin*, *Psyché*, and *La Comtesse d'Escarbagnas*, appeared in 1671, none of them demanding very special mention, with the exception of some exceedingly amusing pieces of dialogue in the *Fourberies*. It is in one of these that the avaricious father utters the celebrated phrase, "Que diable alla-t-il-faire dans cette galère?" with such passionate importunity and ludicrous effect. The following year brought a richer specimen of Molière's art in *Les Femmes Savantes*, acted on the 11th March 1672, consisting of a regular comedy in five acts, which has always been considered one of his most powerful productions. The object of the dramatist's ridicule on this occasion was the scientific airs and learned

Molière.

Molière. dignity which the exploded coteries of the *précieuses* now affected, instead of the romantic jargon in which they had formerly indulged.

We now come to speak of the *Malade Imaginaire*, a piece possessing the melancholy interest of being Molière's last. This play appeared in February 1673, and consisted of a powerful and pungent satire upon those unworthy members of the medical faculty who were accustomed to take advantage of the unfounded apprehensions of their patients. Molière had always been of a delicate constitution, and had for many years been liable to pulmonary affections, which, during the composition of this his last work, increased greatly in violence. His friends attempted to dissuade him from appearing in the character of Argan when the piece came to be represented, as the exertion of voice and person called forth on such an occasion would tend to increase the severity of his malady. But Molière who had sacrificed personal comfort so often for the benefit of those dependent on him, could not forget even in the hour of death "those fifty people who must want their daily bread if the spectacle is put off." He had accordingly appeared as Argan, the *Malade Imaginaire*, for the fourth time; and before the conclusion of the piece, through which he had laboured with great pain, his cough overcame him, and being threatened with choking, he was carried off the stage and conveyed to his own house. The clergy were summoned, but in vain: it was the author of *Le Tartuffe* who was dying, and the last offices of religion must be withheld. Two poor Sisters of Charity, who in past days had never come to his door in vain, try to smooth the pillow of the dying man with their words of peace. His cough soon returned with increased violence, and having burst a blood-vessel, he died apparently of suffocation on the 17th of February 1673, in the fifty-second year of his age. The cunning hand is now stiff, and the inventive brain cold, yet bigotry must have its revenge. Ecclesiastical sepulture was refused the comedian's remains by Harlai, Archbishop of Paris, a man who, after a life of licentiousness, himself died of debauchery. How could the dust of a poor comedian, who wore out his life in the cause of truth and virtue, find respect at the hands of such a *Tartuffe* as this? Yet such is a specimen of Molière's most malignant foes. The interdict was revoked, however, by the private orders of the king, after tearful importunities on the part of Molière's poor unfortunate widow, who, forgetful of all her follies now, tried to atone, by her sorrowing anxiety for the honour of the dead, for the many wrongs she had done the living. It was nevertheless with great difficulty that the remains of one of the truest men France had known were ultimately got interred in the cemetery of Saint Joseph. Of Molière's three children, only one, a daughter, born in 1665, survived him. She eloped with a widower twelve years after her father's death, and died without issue in 1723.

We know nothing respecting the character of Molière that is not greatly to his honour; and those who have been loudest in their censures of the poet have failed to find a flaw in the character of the man. Numerous anecdotes of unquestionable authenticity abundantly prove him to have been an honest, generous, true-hearted man. He seems to have had a genuine love of truth, an utter scorn of whatever was false or mean, a genial, kindly nature, and a heart full of unostentatious benevolence. Baron, a distinguished pupil of Molière's, requested on one occasion some pecuniary aid from his master on behalf of an unfortunate actor whom Molière had known in the provinces. "How much does he want?" asks Molière. "Four pistoles," was the reply. "Here they are," says Molière, "and twenty besides, that I wish *you* to give him; for I want him to feel it is to you he owes his relief." Witness also his clinging to his craft lest his retirement should damage his *troupe*,

when the Academy proposed to receive him on condition of his dropping the title of "actor." His well-known practice of reading his pieces while in manuscript to his shrewd old housekeeper, Laforet, affords an admirable illustration of the amiable simplicity of his character. That he continued this custom so scrupulously, from the mere desire of trying the effect of his compositions on the good dame, is not at all likely. The success of his profession placed him in a position of comparative opulence, and he was indefatigable in his acts of charity. He did not only rest satisfied with aiding the importunate; he is said to have quietly sought out objects for his liberality among needy sufferers of the humblest rank. No change of fortune could alter the original simplicity of his character. The king treated him constantly with respect, and even with familiarity; and not a few of the haughty noblemen of the court, forgetting the accidents of birth in the presence of genius, diligently sought his society. Yet amid all these flattering marks of distinction, Molière preserved the native purity of his heart and the simplicity of his manners. His hours of leisure he enjoyed in the society of the most distinguished literary men of the age; and he counted among his friends La Fontaine, Boileau, Chapelle, and Racine. In society he was very reserved, being characterized by a thoughtful modesty, which gained for him the sobriquet of "The Contemplator."

The most distinguished critics among Molière's countrymen have been unanimous in assigning him the highest place among the comic authors of France; and Voltaire does not hesitate to pronounce him the most eminent writer of comedy of any age or country. This judgment the majority of English critics have also learned to indorse; and even with the extraordinary comic powers of Shakspeare before them, feel it their duty to vindicate for Molière the very highest place of any who has ever distinguished himself in this department of literature. The comic scenes of the great English dramatist are introduced more to relieve the severity of his tragedy, than with the view to make comedy his ultimate aim; and even in the *Merry Wives of Windsor*, his nearest approach to a regular comedy, he rises at times, by the uncontrollable soaring of his genius, into a region of poetry entirely beyond that sphere where vice is satirized and folly rendered ridiculous. Molière, again, hardly ever introduces a single piece of poetical imagery to ornament his dramas. He wrote constantly to the understanding, and not to the imagination. You search in vain almost for any touch of the sublime in his compositions; and even when he becomes serious, he seldom parts company with the hardest common sense. Yet there is no comic author who has depicted character as Molière has done,—keeping steadily fixed before him the grand end of his art. His observation was so penetrating, and his glance so keen, that no veil could hide vice from his detection, or cover the foibles of men from the fire of his wit. His insight into human nature is powerful and penetrating; his delineations are characterized by great truth and simplicity; and his language stands unrivalled for force and *naïveté*. The scenes from which Molière painted represent follies of a former date; yet so profound was his knowledge of the human heart, that while apparently ridiculing an accidental folly, or branding a particular vice, he was at the same time steadily directing his satire against those outstanding follies and vices which are peculiar to man at all times and in all places. And here Molière ceases to be merely the comic writer of France. His works, like those of all men of true genius, become the property of universal humanity. His comic power was of the very highest order, and his wit of the purest kind; his laughter is always hearty, and his pleasantry always innocent. In exposing the more serious forms of vice, his satire occasionally assumes a gravity almost too staid for the ordinary

Molina.

notions of comedy; for virtue, with Molière, never ceases to be sacred, and the keenest shafts of his satire are directed against its enemies. His verses, while remarkable for freedom and fluency, are said to have been polished with great care. He has been charged with deficiency in the development of his plots; with not only precipitating the *dénouement*, but with bringing it about without a sufficient regard to probability. It must be admitted that Molière always takes greater interest in the unfolding of character than in following out the complicities of intrigue. Situation and incident seem always to have held a subordinate place in his estimation. His most striking situations were not his own; yet he compensated by originality of execution for what he had borrowed in design. It signified very little to Molière what was the mere form which his drama assumed; his unrivalled power in portraying individual character, and his genuine comic genius, won for him success alike in regular comedy and in *comédie-ballet*. There is perhaps no instance on record in which such a constant and determined warfare against vice and folly was sustained by means of wit and satire alone, without any assistance either from sublimity or pathos. Molière was a genuine reformer; and the author of *Tartuffe* and the author of the *Lettres d'un Provincial* take their places together as the two most valiant defenders of the truth during the seventeenth century in France.

Of the numerous editions of Molière's works which have been published, the following are the most valuable:—That of Lagrange and Vinot, Paris, 1682, in 8 vols. 12mo, and that of Didot, Paris, 4 vols. 8vo (edition Lefevre), 1854, with notes, historical and critical, and life by Lagrange, who was an actor in Molière's *troupe*. A complete translation of the comedies of Molière, printed with the original French, by James Miller and Henry Baker, appeared about 1750.

For the most valuable information respecting the life and works of Molière, see *Vie de Molière*, par M. Taschereau, new edition, Paris, 1854; *Notes Historiques sur la Vie de Molière*, par M. Bazin, Paris, 1851; also an able essay on *The Life and Genius of Molière* in the *Cambridge Essays* for 1855, by Mr C. K. Watson. (J. D.—S.)

MOLINA, LOUIS, the founder of the sect of the *Molinists*, was born at Cuença in New Castile in 1535. At the age of eighteen he entered the Order of Jesus. He then studied at Coimbra, and was subsequently appointed to a theological chair at the Portuguese university of Evora. During twenty years he taught there with great success, and acquired some reputation for the lively and subtle ingenuity which he displayed in his commentaries on Thomas Aquinas, and his treatise *De Justitia et Jure*. But the work which especially rendered him famous was his *De Concordia Gratiae et Liberi Arbitrii*, folio, Lisbon, 1588. It is an attempt to show, by a method somewhat new, how the doctrines of predestination and grace are consistent with free will. Assuming that man is free to perform or not to perform any action whatever,—that, in fact, he really works out his own destiny,—Molina yet affirms that this circumstance renders the bestowal of the grace of God neither impossible nor unnecessary. It does not render it impossible, for God never fails to bestow grace upon those who ask it with sincerity. It does not render it unnecessary, for grace, although not an efficient, is still a sufficient cause of salvation. Nor does it preclude the possibility of predestination. The omniscient God, by means of his *scientia media*, or power of knowing future contingent events, foresees how we shall employ our own free will and treat his proffered grace. Therefore, upon this foreknowledge, he can found his predestinating decrees. Such doctrines as

these brought upon their author the attacks of the Dominicans, who were the faithful followers of Thomas Aquinas. The Jesuits came to the defence of one of their own order. A hot war of theses then ensued, which speedily excited Spain into a ferment, and forced Clement VIII. in 1594 to impose silence upon the clamorous combatants. But the orthodox fury of the Dominicans refused to be calmed. They insisted that the grand inquisitor Cardinal de Quiroga, Philip II. of Spain, and the pope, should each interpose his authority to check this revival of Pelagian heresies. At length in 1598 Clement referred the dispute to a council consisting of a presiding cardinal, three bishops, and seven theologians of different fraternities. For several years this court continued to hold its meetings, which, as they bore reference to the aids of grace, were called *Congregationes de Auxiliis*. Its decision was given in 1601 in favour of the Dominicans. Clement therefore prepared to pass a sentence of condemnation against the Molinists; but the Jesuits prevented him, and induced him in 1602 to summon a council under his own presidency for the reconsideration of the dispute. This council was interrupted in its deliberations by the death of Clement in 1605. It resumed its sittings, however, under the following pope, Paul V., and continued to deliberate until the controversy was, by common consent, left undecided. Meanwhile Molina had died at Madrid in 1600. The dispute between his followers and the Dominicans was afterwards merged in the great controversy between the Jesuits and the Jansenists.

MOLINOS. See MYSTICISM.

MOLISE, or SAMNIO, a province of Naples, bounded on the N. by Abruzzo Citra, E. by Capitanata, S. by Principato Ultra, and W. by Terra di Lavoro; having an average length of 55 miles, a breadth of 40 miles, and an area of 1783 square miles. The province is situated on the E. slope of the Apennines, the main ridge of which traverses it from N.W. to S.E., and sends off several branches in a northeasterly direction. The surface is thus for the most part rugged and mountainous; but the valleys and the lower parts of the hills are fertile, though ill cultivated; and the higher regions afford excellent pasturage. The principal rivers of the province are the Trigno, the Biferno, and the Fortore, all of which flow from the Apennines to the Adriatic. The chief productions of the province are,—maize and other sorts of corn, pulse, rice, oil, wine, and fruits. Sheep, goats, swine, and a small number of horned cattle are reared; but the breeds are inferior. Bees are also reared in large quantities. The most important manufactures of the province are those of cutlery and firearms; the principal seats of which are Campobasso, Frosolone, Lucito, and Agnone. The inhabitants are for the most part sunk in poverty; and thefts and murders are more common here than in most other parts of Italy. The province of Molise corresponds to the lands of Larinum, of the Caraceni, and of the Pentri, in ancient times. It is now divided into three districts,—Campobasso, Isernia, and Larino, comprehending 33 arrondissements and 136 communes. Pop. (1854) 376,750.

MOLITERNO, a town of Naples, province of Basilicata, situated on the E. slope of the main ridge of the Apennines, near the source of the Agri, 10 miles N.N.E. of Lagonegro. Pop. 5000.

MOLL, a town of Belgium, province of Antwerp, on the right bank of the Moll-Nethe, 31 miles E. of Antwerp. The town contains several churches and schools, an hospital, and a prison. The principal manufactures carried on are,—brewing, distilling, dyeing, and the making of woollen stuffs, hats, leather, tobacco, and bricks. Pop. 4770.

MOLLUSCA.

Introduction.

OF the Primary Division, or Province, of the Animal Kingdom, which is the subject of the present Article, Aristotle first defined certain members, under the name "Malakia," of which "Mollusca" is a rude Latin equivalent.

The great and peculiar merit of the system of Cuvier, as exemplified in the *Règne Animal*, and especially in the last edition (1830) which came from the hands of the illustrious author, is the determination of the characters and boundaries of the molluscous province by investigations of the entire animals.¹

Most Mollusks are protected by a shell, and the shells had monopolized the attention of most preceding classifiers. After Cuvier, "Conchology" sank to its proper position as an artificial system and a subordinate department of "Malacology." By *Malacology* is meant the science of the "Malakia," *Mollusca*, or Mollusks; as "Ichthyology" is that of the *Pisces*, or Fishes. We now, in English speak of "a mollusk" and of "mollusks," as the French of "mollusque" and "mollusques." Subsequent advances in the knowledge of *Mollusca* have been made chiefly by pursuing the anatomical methods of Cuvier, and by applying them, not only to the last or fully developed stage of the individual, but to the previous stages of its development, from the egg onwards. These embryological investigations have required the use of the microscope; and Malacology, like other branches of natural history, has benefited by the application of the higher powers of that instrument to the investigation of both the minute embryos and of the component tissues of the organs of the Mollusks.

The first important improvement in the characters and constitution of the province or sub-kingdom of Mollusca; as defined by Cuvier in 1794² and 1817,³ was the elimination therefrom of the order *Cirripedia*. In 1819 Straus Durckheim, in a memoir on the Structure and Affinities of an Entomostracous Crustacean (*Daphnia*), published in the fifth volume of the *Mémoires du Muséum*, compared in detail the organization of a Cirriped (*Pentelasmis*) with that of an Entomostracan (*Limnadia*), and pointed out their close affinity; which affinity was, two years after, insisted upon and illustrated by the correspondences of structure between *Pentelasmis* and *Daphnia*, by Mr W. S. Macleay, in his *Horæ Entomologicae*, part i., p. 308. Dr Gray accordingly omitted the *Cirripedia* from the "Systematic Arrangement of the Mollusca," which he published in the *London Medical Repository*, vol. xv., 1821, p. 229. But the capital discovery, proving the plan of structure and the essential nature of the *Cirripedia* to be "articulate," not "molluscous," was made by Mr J. V. Thompson, and was published in 1830 in the third part of his *Zoological Researches*. His observations were made on the larvæ of a small sessile barnacle (*Balanus pusillus*), which he showed to undergo a very remarkable metamorphosis. He captured their larvæ in a fine towing net, as they swam freely in the guise of a small Crustacean furnished with a flexible shell composed of two valves like those of *Daphnia*. Being preserved alive in a vessel of sea-water, these larvæ cast off their bivalve

Introduction.

shell, attached themselves to the bottom of the vessel, and became transformed into the *Balanus pusillus* of Pennant. Whilst the young animal possesses the natatory limbs and the power of locomotion, it has a pair of compound eyes, which gradually become obliterated, as in the case of the crustaceous *Cymothoe*, in the final transmutation to a fixed and sessile state. Other phenomena detailed by Mr Thompson left no doubt that the homogangliate type of the nervous system of the *Cirripedia*, first made known by Cuvier,⁴ most truly indicated the primary group or province of the animal kingdom to which that singular class of shell-clad animals belonged.

Burmeister, who corroborated the discovery of Thompson, formally proposed, in his work on the Cirripeds, published in 1834, to transfer them to the Articulate province, and to place them as a particular tribe in the class *Crustacea*.

De Blainville had indeed included the Cirripeds with the Chitons in a distinct sub-class called "Malentozoaires," under which name they are described, as the order *Nématopodes*, in the work on Mollusca called *Malacologie*, which was published as such in 1825. But the obvious want of anatomical knowledge, or indifference to evidence from organization, which the association of the Cirripeds with the multivalve Gastropods displayed, prevents the attachment of any importance to the innovating ideas and sweeping changes of malacological nomenclature proposed by this naturalist.

For the same reason, no influence on the modification of molluscous classification was exercised by the suppression of Cuvier's order *Pteropoda*, and the intercalation of the genera of that order between *Helix* and *Fissurella* amongst the Gastropods of Cuvier, in the *Manuel de la Malacologie* of 1825 above cited. Even as late as 1837 Professor Milne Edwards, in his *Eléments de Zoologie*, adopts the constitution and relative position of the *Pteropoda* assigned to them by Cuvier in the last edition of the *Règne Animal*; and their position is preserved unchanged in the second volume of the *Zoologie de la Bonite*, published by M. Souleyet in 1852.

But before noticing the chief modifications of the Cuvierian system in reference to minor groups within the limits of the Molluscous province, it may be remarked, with reference to those limits, that had Cuvier placed due reliance on the character of the nervous system which had previously guided him in his primary arrangement of the animal kingdom, he might have been led by his discovery, in 1815, of the homogangliate type of that system, in both sessile and pedunculate barnacles, to the reform subsequently worked out by Straus Durckheim and others.

The modification of two of Cuvier's provinces by the subtraction of the class *Cirripedia* from one, and the addition of these soft inarticulate conchiferous animals to the other, induced Professor Owen, in the Synopsis of his course of Lectures delivered at St Bartholomew's Hospital, and published in 1835, to propose the term *Heterogangliata* for the so-curtailed Mollusca, and *Homogangliata* for the pro-

tion.

Characters
of the Mol-
lusca.

portionally expanded Articulata,—terms expressive of the leading modifications of the nervous system characterizing those provinces respectively. The term *Mollusca* is used in the present article, as by most recent authors, in the sense of the *Heterogangliata* as above defined.

The *Mollusca* are here meant to include the animals with one ganglion or more below the entry to the alimentary canal, whence nervous chords radiate to form a collar round that entry, and to supply other organs of the body; nervous ganglions being superadded, as the species ascend in complexity of structure, above the gullet, representing a brain, and in different parts of the body, but commonly in a more or less scattered or unsymmetrical manner, and never along a pair of symmetrical sub-abdominal median chords.

In the highest molluscan class (Cephalopods) muscles may originate from an internal cartilage; in other Mollusks they are attached to the skin or to the shell which may be developed in that otherwise soft substance. The shell is hardened chiefly by carbonate of lime, and consists either of one piece or two pieces, called "valves;" rarely of more than two, or with accessory parts. The blood is colourless, or not red; the heart is distinct, muscular, and propels the blood through a system of arteries and veins, the latter having more or less the form of irregular sinuses or lacunæ. The respiratory cavity, with the exception of one family (Ascidians, which therefore ought rather to be transferred to the molluscoid Zoophytes), receives or opens near the anus. The intestine is usually bent or reflected forward to effect that relation. The *Mollusca* may be either dioecious or hermaphrodite. The molluscoid Zoophytes are parthenogenetic.

The foregoing characters of the Molluscan province are natural, if the Ascidians and ascidioid Polypes are excluded. Admitting these as the lowest confines of the province, its definition must be qualified by large exceptions.

Boundaries
of the Mol-
lusca.

Cuvier, in publishing the collected results of his anatomical investigations of the *Mollusca*, remarks in the preface:—"Here may be seen to what point some among them approach the vertebrate animals, and one may convince himself that it is no longer possible to leave them, as Linnæus did, in the lowest class of the animal kingdom confounded with the tentaculiferous Polypes and other as simple Zoophytes."¹

Savigny² was the first to show that such linking on of the molluscous to the polype type of structure was not so impossible in nature; this he did by his discovery of the organization of the compound Ascidians which had previously been classed with Zoophytes.

Audouin and Milne Edwards,³ Ehrenberg,⁴ Thompson,⁵ and Arthur Farre,⁶—the last-named author more especially,—have demonstrated the resemblances in organization between the compound Polypes with ciliated tentacles and the compound Ascidians.

These results of anatomical investigation, carried out into forms of a lower grade than the Mollusks dissected by Cuvier, together with subsequent embryological observations demonstrating certain developmental characters which

the nudibrachiate and ciliobrachiæ Polypes have in common with the Ascidians and higher Mollusks, have led some modern naturalists to return to the Linnæan views of classification, and to group together, for example, under the term "Allovitelliens" the *Mollusca* and *Radiata* of Cuvier.⁷

Introduc-
tion.

The truth is, that with regard to any great primary group of animals, as with a tree, it is much more easy to define the summit than the base; nay, although the labour in quest of the beginning be like that of following out all the hidden ramifications of the tree's root, it will fail to end in as definite results, and the lower boundary of the *Mollusca*, as of the *Articulata*, must still be defined by an arbitrary line.

One has no difficulty in regard to the highly organized Cephalopods, in concluding that we have reached the top-most branches of the molluscous tree. We cannot connect them with the *Sagitta* or *Amphioxus*, nor glide on from them to any low embryonoid form of vertebrate life; but, in descending from the cephalopodous summit we are led, through the Nautilus, the siphonated Univalves, and the naked Gastropods, to minute forms of the latter in which all traces of shell, of foot, of liver, and of gills, have disappeared, and in which the alimentary canal, dispersing ramifications throughout the body, combines digestive, hepatic, and excretory functions, as in some *Entozoa* (fig. 1, *e*, *c*),

and in some fresh-water worms, with a ventral disc *d*, called *Planaria*, to which the marine *Apneusta* (fig. 2) are more closely allied than to any of the Pteropodous, Lamellibranchiate, Palliobranchiate, or Tunicate types of the *Mollusca*. Thus one of the roots of the Mollusca appears to be lost in the Turbellarian and Trematode families of Abranchiate Vermes.

The *Brachiopoda*, by the more intimate organic union of their shell and mantle, and by their ciliated, fringed,

¹ "On y verra à quel point plusieurs d'entre eux se rapprochent des animaux vertébrés, et l'on se convaincra qu'il n'est plus possible de les laisser, comme l'avait fait Linnæus, dans la dernière classe du règne animal, confondu avec les polypes à bras et d'autres zoophytes aussi simples." ⁷ "Il nous semble que la division de Linnée est encore la plus naturelle. Elle est en effet le plus en harmonie avec le développement." "Chez les vers de Linnée, dont Cuvier a fait les Mollusques et les Radiaires, le vitellus ne rentre par le dos ni par le ventre; on pourrait les désigner sous le nom de *Allovitelliens* ou *Alloctyledones*. Les *Allovitelliens* comprennent la classe des Mollusques, des Polypes, des Echinodermes, &c." (Van Beneden, *Embryogenie des Bryozoaires*, 4to, 1845, p. 7.)

Introduction.

bent or spiral arms, compared by Siebold to those of *Alcyonella*, conduct to certain forms of *Bryozoa*, to which they are more closely allied than is the *Salpa* or *Ascidia*. The progress to the latter form of Mollusk may be traced upwards as follows:—

Amongst the varied forms of microscopic beings called *Infusoria* and *Polygastria* is one (fig. 3, *A*) shaped like a bell, attached by a contractile apical peduncle to a foreign body, with the base of the body provided with vibratile cilia, effecting the respiratory currents of the surrounding water, and drawing the food towards the mouth, which, with the vent, open upon the same ciliated extremity of the body. The ciliated border is retractile. This organism propagates, among other modes, by buds (fig. 3, *B*), which become detached, and for a time swim freely as "ciliated gemmules (fig. 3, *C*)."

In another minute aquatic organism, with a similar form and pedunculate attachment (fig. 4), there is a certain

Fig. 3.
Vorticella convallaria.

Fig. 4.
Pedicellina.

advance in development, with concomitant distinction of parts. The vibratile cilia are supported on tentacular prolongations *g* of the free base of the bell-shaped body *A*. The cavity *cd* receiving and acting on the food, is now distinct from the proper walls of the body, and can be traced, as a canal, extending from the mouth *c* to the vent *d*, both of which, however, open, as in the *Vorticella*, within the ciliated circle. The contractile fibres *m*, which retract the ciliated borders, are manifest.

The organisms showing this advance of structure are called *Bryozoa* and "ciliobranchiate Polypes." They pro-

pagate by buds *B*, and by free-swimming ciliated gemmules *C*. The generic form here illustrated is called *Pedicellina* (fig. 4).

A third type, or what, in regard to general development, might be called a third stage (fig. 5), is manifested by a

Introduction.

Fig. 5.
Perophora listeri.

group of small aquatic animals called Ascidians, for the most part compound, and in some species pedunculate, as in the two preceding stages; the peduncle being attached to the apex or end of the body opposite to that on which the mouth and vent open. But in the present more advanced type the walls of the body are so developed as to surround separately the oral (*g*) and anal (*f*) apertures; rudiments of ciliated tentacles *g* are confined to the oral inlet, and the cilia, which answer in function to those of *Pedicellina* and *Vorticella*, are developed from a capacious sac *cc*, with transverse rows of holes, at the lower part of which the alimentary canal begins; this canal *d* returns upon itself, as in the former more simple types, and terminates at *h*, below the anal aperture of the body *f*. A rhythmically contracting or pulsating body exists in all the three grades of structure above cited. In the Ascidian type the heart *n* manifestly circulates a nutritive fluid through two channels, marked by arrows in fig. 5, which convey it in opposite directions along the stem, which thus organically unites the different individuals supported by its branches.

The Ascidians propagate by buds (*B*) and by eggs, the latter excluding free-swimming larvæ *C*, shaped like the tadpole of the frog. This well-marked developmental distinction has not received from some naturalists the importance it merits in the question of associating the *Bryozoa* with the *Tunicata*.

As to their relations to the true *Mollusca*, some classifiers draw the line between the first and second steps of development; others between the second and third. One physiologist¹ assigns developmental or embryonic facts in support of an incorporation of all *Zoophytes* with the *Mollusca*; another physiologist² would associate the rhizobranchiate and ciliobranchiate *Acalephæ* with the *Salpæ* and other acephalous *Mollusca*. The philosopher who may, in the range of his studies of animated nature, include the highest phenomena of life—the psychical—will be apt to believe that the systematist who is really least qualified will denounce most dogmatically every partition which does not tally with his own notions of the proper boundary line.

It is here proposed to submit that the *Mollusca*, for the

¹ Van Beneden, *loc. cit.*
VOL. XV.

2 s

Introduc-
tion.

ends of definition and description, should be understood to commence, in the ascending order, with those forms in which the respiratory organs or cavity are in relation rather with the vent than with the mouth. The oral relation with the ciliated or tentaculiferous circle prevails from the *Vorticella* and *Hydra* to the *Ascidia* and *Terebratula* inclusive; but the bend of the intestine in *Discina* and *Lingula* indicates the tendency to the usual molluscan relation of the vent in the *Brachiopoda*.

In deference, however, to the expectation of most readers, and with the conviction, when the progressive series of developments to different modifications of the molluscan type have been traced and illustrated, of the essential unimportance and artificiality of any line defining the lower boundaries of the heteroganglionic province, the present article will include, with the anal-breathing classes, the *Tunicata* and *Brachiopoda*, although these are rather "Mollusoid" than *Mollusca*.

Classes.
Subdivi-
sions of
Mollusca.

Having premised so much as to the definition and extent of the molluscan or heteroganglionic province, the subject of its partitions, and of their relative value in the scale of organization, is next in order.

In tracing the progressive complication of animal structures from the simplest forms, we soon find ourselves travelling along two distinct routes, the additional complexities adjusting themselves according to two general types of organization, which are, however, so gradually assumed, that the lower boundary must in both cases be arbitrarily defined.

In the great province of the *Articulata* the advance of structure is most conspicuous in the organs peculiar to animal life, and is manifested in the powers of locomotion, and in the instincts which are so various and wonderful in the insect class.

In the *Mollusca* the developmental energies seem to have been expended chiefly in the perfection of the vegetal series of organs, or those concerned in the immediate preservation of the individual and the species.

The *Mollusca* are so called on account of the soft unjointed nature of their external integument. The scattered centres of the nervous system, disposed according to the heteroganglionic type of that dominant system of organs, is often accompanied with an unsymmetrical form of the entire body, which, in compensation for the low condition of the perceptive energies, is protected in most of the species by one or more dense calcareous plates, called shells.

All true Mollusca have a complete alimentary canal, with mouth, stomach, intestine, and vent; and they are provided with circulating and respiratory organs.

In a large proportion of the lower organized Mollusca there is no head and no brain or superoesophageal ganglion. The inlet for the food is simply a pharynx, or beginning of the oesophagus, without jaws, tongue, or mouth, properly so called. All other Mollusca are provided with a head, which generally supports feelers, or soft tentacula, eyes, and a mouth armed with parts for mechanically operating on the food.

The molluscan province may thus be primarily divided into *Acephala* and *Encephala*.

The *Acephalous* Mollusca are all aquatic, and are divided into classes according to the modifications of their integument, or of their gills.

The *Tunicata* are those which are inclosed by an elastic cellulose uncalcified integument. They breathe either by a vascular ciliated pharyngeal sac, or by a riband-shaped gill stretched across the common visceral cavity. John Hunter, who had anatomized the typical forms of this

class, and had recognised the homology of their flexible case to the shells of the bivalves, to which Mollusks he saw that Banks's "Dagya," and the "squirters" of our own shores, were most nearly allied, grouped together the *Salpæ* and *Ascidie*, as they are now called, into a natural family, which he termed "Soft-shelled."¹ This family is the same as that afterwards described and called "shell-less *Acephala*" by Cuvier, and *Tunicata* by Lamarck. All the other *Acephala* have a bivalve shell.

The *Brachiopoda* have two long spiral arms developed from the sides of the mouth, and respire chiefly by means of their vascular integument or "mantle." One valve of the shell is applied to the back, and the other to the belly, of the animal, which is attached by its shell, or by a pedicle, to some foreign body.

The *Lamellibranchiata* are bivalve conchiferous Mollusks, which respire by gills in the form of vascular plates of membrane attached to the inner surface of the mantle. One valve is applied to the right side, the other to the left side, of the animal. The common oyster and mussel are examples of this best-known class of *Acephalous* Mollusks.

The *Encephalous* Mollusca are divided into classes according to the modifications of the locomotive organs.

The *Pteropoda* swim by two wing-like muscular expansions, extended outwards from the sides of the fore part of the body.

The *Gasteropoda* creep by means of a muscular disc attached to a greater or less extent of the under part of the body.

The *Cephalopoda* have all or part of their locomotive organs attached to the head, whence they radiate in the form of muscular arms or tentacula.

In the last class only do we find, in the present series of animals, an internal skeleton, combined in some with a shell. In the rest of the Mollusca the hard parts, where present, are external. But the integument in certain species of the *Encephalous* classes, and in most of the *Cephalopoda*, is uncalcified and flexible.

The chief modification of the Cuvierian system, in regard to the sequence or relative position of the classes of the *Mollusca*, has been made in the *Encephalous* division, and consists in the transference of the *Pteropoda* from above to below the *Gasteropoda*.

The grounds for this change, which, as already shown, was not accepted up to 1852, rest mainly upon a demonstrated nearer affinity of structure of the *Cephalopods* to the *Gastropods*, and on the resemblance of the mature form of the *Pteropods* to the larval stage of certain *Gastropods*.

The first step in the work requisite to establish the necessity of this innovation upon the Cuvierian system will be found in the following passage from Owen's *Memoir on the Pearly Nautilus*:²—

"The interesting character which the *Nautilus* sustains as an osculant form between *Cephalopoda* and *Gasteropoda*, will perhaps be considered to have been sufficiently manifested by the instances of affinities already cited; but it is rendered still more evident on a consideration of the nervous system. The forms, proportions, and disposition of the principal masses of this system appeared, indeed, at first sight to recede so far from the type of the higher *Cephalopods* as to have rendered it necessary, in the description, to refer to a *Gasteropodous* genus in illustration of it. The essential difference, however, as has already been shown, consists in the simpler condition of the central mass; the source of volition being thus in harmony with the diminished energies of the muscular, and the contracted sphere of the sensitive system.

"The differences in the distribution of the principal

Introduc-
tion.

Intro-
duc-
tion.

nerves are not less important in a physiological point of view. In the Cephalopods, whose shells are rudimentary and internal, and whose bodies are enveloped in a naked, and, as we must suppose, sensible mantle, the nerves which supply that part radiate from a ganglion, which, as in the posterior roots of the spinal nerves in the *Vertebrata*, is interposed on the cord which brings them in communication with the central mass. In *Nautilus*, on the contrary, whose body is incased in an insensible calcareous covering, the analogous nerves are wholly expended on the largely-developed muscles which attach the shell to the body; and these nerves, like the motor filaments of the spinal nerves, pass into the muscles directly from the brain without the interposition of any such ganglion.

"The inferiority of the more intellectual senses, sight and hearing, is in correspondence with the simplicity of the brain; and in receding from the higher Cephalopods in the structure of the eye, it inclines more directly towards the Gastropods, numerous genera of which, and especially the *Pectinibranchiata* of Cuvier, present examples of this organ analogous in simplicity of structure, and in a pedicellate mode of support and attachment to the head. As the pearly nautilus, like the latter group of Mollusks, is also attached to a heavy shell, and participates with them in the deprivation of the locomotive instruments of the Cephalopods, we may thence deduce the more immediate principle of their reciprocal inferiority with respect to the visual organ; for what would it avail an animal to discern distant objects which could neither overtake them if necessary for food, nor avoid them if inimical to its existence?

"As the spheres of vision and of action, however, are thus limited, the power of taking cognisance of proximate objects is proportionably augmented, and the organs of the simpler sense of touch are more amply developed. In the numerous and singularly-disposed tentacles of *Nautilus*, we have also examples of a recurrence of structures heretofore unknown among the Cephalopods, and whose analogues are to be sought for in inferior groups. And here again, as in the case of the eye, after searching in vain among the Pteropodous genera, we are compelled to admit the claims of the Gastropods to a closer alliance with the highly organized class whose affinities the pearly nautilus has tended so materially to elucidate. Thus *Doris*, *Tethys*, and *Tritonia* each present examples of sheathed and retractile tentacula; and in the former of these genera they have the same peculiar structure as is displayed in the ophthalmic tentacles of *Nautilus*." (See Cuvier, *Mém. sur le Doris*, p. 12, pl. 2, fig. 1.)

"On a consideration of the generative system, it will appear that, as far as regards the female, the pearly nautilus does not recede materially from the Cephalopodic type; and it may be remarked that the *Pectinibranchiata*, in their dioecious mode of generation, approximate closer to *Nautilus* than the other *Gasteropoda*, and present a similar laminated glandular organ in the branchial cavity, whose office is supposed to be to secrete the receptacles of the ova after they are expelled.

"The retractile tentacles of *Clio* are constructed on a plan very different from those of *Nautilus*. The consideration, indeed, on which the *Pteropoda* have been placed in the *Règne Animal* next in order after the *Cephalopoda*, and preceding the *Gasteropoda*, appear to be slighter than have usually influenced the immortal author of that work in the position of his groups. Their swimming like the former animals is a relation of analogy; whilst their inferiority to some, at least, of the Gasteropodous families is evidenced by the doubtful nature of their organ of vision, and by their hermaphroditical mode of generation."

Intro-
duc-
tion.

Influenced by these views, the author of the work above cited placed the *Pteropoda* below the *Gasteropoda* in the Synopsis of his Lecture on Comparative Anatomy, published in 1835. The *Pteropoda* have the same position in the two editions (8vo, 1843 and 1855) of his *Lectures on Invertebrate Animals*.

Mr Woodward has adopted the same sequence of the classes of encephalous Mollusca in his Excellent, comprehensive, and accurate *Manual of the Mollusca*, 8vo, 1851-1856; and it has received the sanction of Professor Van der Hoeven in his *Handbook of Zoology*, second edition, 1855. Thus the position originally assigned by Lamarck¹ to the *Pteropoda* below the *Gasteropoda*, by which they are separated from the *Cephalopoda*, is that which appears now to be generally adopted; and it is perhaps to the genera *Bullæa* and *Gastropteron*, and to the *Firolidæ*, that the different forms of this interesting group of floating Mollusks present the closest affinity.

With regard to the subdivisions of the classes, Cuvier has left little of importance to be proposed in the way of amendment; but some innovations have obtained partial acceptance which seem to be retrograde steps.

In the Lamellibranchiate class (the "*Acephales Testacés*" of the *Règne Animal*) the extent to which the mantle-lobes are united and developed, the number and position of the adductor muscles, the presence and form of the foot, are still the characters which are chiefly relied on for distinguishing the primary groups of the class.

In the *Gasteropoda*, Cuvier believed that the modifications of the respiratory organs, especially as to position and form, best indicated the orders of the class. The absence, however, of an articulated skeleton—internal or external—permits the softness of the body of the Mollusk to adapt itself to a greater diversity of undefined and unsymmetrical shapes than is possible in the *Articulata* or *Vertebrata*; and hence the relative position of certain organs become changed in a degree beyond anything observable in the primary divisions of animals of more fixed forms. The branchiæ, which, in a vermiform Gastropod like the *Doris*, may project backwards behind the heart, will be found, where the hinder part of the body has to be lodged in the spiral whirls of a shell, to be tilted forwards as by an act of rotation, so as to project forwards and lie in advance of the heart; as, e.g., in the whelk. It has been accordingly proposed to make this really unessential character, founded on relative position and direction of the gills to the heart, override the more important differences in the extent and relative position of the gills to other parts of the body, and also the structure of the gills themselves; and the order *Prosobranchiata*, in the system of Professor M. Edwards, includes all those Gastropods in which the gills lie in advance of the heart, and thus associates the whelk in the same order with the limpet, and with such floating forms of Gastropod as the *Firola* and *Carinaria*; all other gill-bearing Gastropods being "*opisthobranchiate*." But in reference to the latter term, the student who may anatomize the species which it is proposed to include, will find it to be in many instances an arbitrary, if not an incorrect one. In *Glaucus*, for example, the gills are external, supported on pairs of processes progressively diminishing in size from before backwards. The heart is situated opposite the middle pair, consequently behind the largest and chief pair; yet the *Glaucus* is classed with the Gastropods, which have the gills behind the heart. In *Diphyllidia* the heart is near the middle of the body; the gills, commencing near the mouth, extend along each side of the body. In all the Nudibranchiates with branchial tufts some of the pairs are always in front of the heart; and in general, as far as this inde-

¹ *Histoire Naturelle des Animaux sans Vertèbres*, vol. vi., 1818. The absence of any adequate reason for the change in the position of the *Pteropoda* proposed in this work caused the views of Cuvier to maintain their sway until a comparatively recent period.

Introduc-
tion.

finite character is concerned, the *Nudibranchiata* are as entitled to be called "Prosobranchiates" as "Opisthobranchiates."

Some Pteropods are "prosobranchiate;" many might be termed "opisthobranchiate;" but species of the same genus—*Cleodora*, e.g.—would perplex the zoologist confiding in the ordinal character in question by their differences in respect to it. In *Hyalea* as much of the gill is in front as behind the heart; and one pulmonary vein passes backwards, the other forwards, to the auricle. The really natural character of the group manifesting these varieties in the relative position of heart and gill, shows the soundness of the judgment of Cuvier in founding his orders of Cephalous *Mollusca* on the more truly important characters of the breathing organ itself. The order *Prosobranchiata*, in the class *Mollusca*, resembles in its vague generality the order of the class *Mammalia*, proposed to be founded upon the discoid placenta.

In regard to a later attempt to generalize molluscan characters according to the course of the alimentary canal, there is less to be said. No care has been taken to distinguish the bend of the intestine which follows and is determined by the part of the body containing it, from the bend of the tube which is independent of any bend or production of the body of the Mollusk. And when the anatomical facts have been too plainly adverse to the proposed classification to be overlooked, they are attempted to be explained away. In the *Pecten*, the *Unio*, the *Lutraria*, and other bivalves, the principal loop of the intestine is open towards the dorsal aspect of the body, or that next the hinge of the shell. But such a bend contradicts the proposed classification on intestinal characters; the author of which is therefore compelled to qualify that principal bend of the intestine as being "accidental." The so-called "neural" Mollusks associate the *Polyclinum*, *Terebratul*, oyster, and *Clio* with the *Sepia*; the "hæmal" Mollusks link the Ascidians with the snails and whelks. One consequence of this classification and nomenclature is to throw doubt on, and to confuse the meaning of, the terms "neural" and "hæmal," which are at once definite and intelligible in regard to the *Vertebrata*, to elucidate the nature of which they were devised, and to which end they ought to be, and doubtless will be, restricted.¹

Homolo-
gies of the
Mollusca.

The hitherto published illustrations² set forth as those of the common plan of structure of the *Mollusca* appear to be premature; there is at least no evidence of their being the result of researches equivalent in number and kind to those which have issued in the most generally accepted views of the archetype of the *Vertebrata*.

The ways that have led to the present state of knowledge respecting the vertebrate archetype have been manifold and painfully pursued. The inquiry commenced with a comparison of the connections, during the phases of development, of particular parts in the different vertebrate animals, with a view to determine how far the parts in one species answered to the parts in another in the sense implied by the term "homology."³

The grounds for the conclusions as to these "special" homologies have been supplied in detail where those conclusions are enunciated. Upon these conclusions have next been founded a higher series of generalizations, under the term "general homologies;" from which have, finally, been deduced the idea of the common plan of structure of the vertebrate province.⁴

Introduc-
tion.

Where special homologies have been arrived at in the attempt to define the molluscan archetype, the results are expressed, according to rule, by the proposition of definite names for the parts so deemed to be determined. Thus a part of the visceral cavity of a Mollusk is called "an abdomen," or a "post-abdomen," as it is placed before or behind the anus;⁵ and this definition is an essential basis of the proposed archetype. A general reference to the results of the investigators of molluscan development is made as a warrant for the safety of the above proposition; but, the particular proofs are not given; and the writer of the present article has failed to find in the authors cited, or in nature, any evidence to warrant the expression that "the visceral mass is thrust out behind the anus"⁶ in any Mollusk.

The growth of the abdomen and intestinal canal, resulting in different relative positions of the anus, is essentially the same in fishes and Mollusks. The different relative positions of germ-yolk and embryo being admitted, the progress of development which places the vent in advance of the visceral mass in the fish, is as little due to a "thrusting out" of such mass as it is in the slug, whelk, or snail. The grounds for pronouncing the part of the abdomen in advance of the anus in a gymnotus, to be the homologue of the part of the abdomen in advance of the anus in an eel, and the part of the abdomen—very considerable in the gymnotus—behind the anus to be a distinct part, are not appreciable by the present writer; he can as little understand the reasons for calling this considerable part of the abdomen a "post-abdomen," and the answerable part, according to the contained viscera and the protective portion of the spine in another fish an "abdomen." The mere varying bend of the gut, and consequent different positions of the vent, are wholly inadequate for such a distinction. There is nothing in the development of a Gastropod that makes the position of the anus more adequate for a distinction between abdomen and post-abdomen than in the fishes above cited. The really important modifications in the development of a pulmonated Gastropod, as compared with a Pectinibranchiate, do not effect an equivalent change in the course of the intestine. In the present article it is held that the large cavity containing stomach, intestine, liver, and generative glands in the *Doris*, is the homologous part with the cavity containing the same viscera in the snail; just as the abdomen in a gymnotus answers to that in an eel, although the vent is at the fore part in the one, and at the hind part of the cavity in the other. The arbitrary division of the great visceral cavity, of a Mollusk into "abdomen" and "post-abdomen," inasmuch as it is called for to support the idea of the molluscan archetype here discussed, augurs as ill for the stability of that idea as the like arbitrary assumptions by Spix and Geoffroy did for the stability of their ideas of the vertebrate archetype.

In the paper in the *Philosophical Transactions*, above quoted, treating of the archetype of the molluscan province, a few other special homologies are enunciated, as, for example, that certain of the cephalic arms—the four next the dorsal aspect—of the cuttle-fish are homologous with the fore-part of the foot in the snail or whelk, the remaining four to the middle part, the superadded tentacles (which arise internal to, and are distinct from, the ordinary arms) to the hind part, the respiratory tube or funnel to the free thickened border of the mantle in the whelk, and to the

¹ See Professor Huxley's paper in the *Philosophical Transactions* for 1853, p. 45, and in the *English Encyclopædia*, art. Mollusca. The same may be said of the term "post-abdomen," borrowed from "Crustaceology," where it has a definite meaning, but not answering to that in which it is applied to Mollusca.

Introduc- wing-shaped fins, or locomotive muscular expansions in the
tion. *Chio* and other *Pteropoda*. The grounds for these special
homologies are not detailed in the paper cited: the con-
clusions themselves are indicated in *Phil. Trans.*, 1853,
pl. v., by the symbols *pp*, *ms*, *mt*, and *ep*, to the four parts,
as above successively enumerated.

The difficulty, not to say impossibility, of assigning adequate proofs for such homological propositions depends upon the principle, that the general substance of a Mollusk, and the absence of internal firm parts, influence or relate to the development of muscular tissue according to a teleological rather than a homological principle,—as when a part for adhesion, a part for creeping, a part for swimming, a part for seizing, a tube for expulsion of fluid, &c., is developed, where wanted, agreeably with the exigencies and the sphere of life of the species. This principle plainly guides such developments, viewing the molluscan province generally, more than that law of adhesion to a common pattern which enables the anatomist to view the wing of the bird, the fin of the whale, the fore-paw of the lion, and the hand of man, as answerable parts,—modifications of the same “diverging appendage.”

Where grounds for determining homologies, like those which support such generalizations in the vertebrate province, are wanting in the molluscan province, it is better to abstain from speaking of parts as “homologous” until sufficient evidence of homology can be assigned.

To call the four dorsal arms of a dibranchiate Cephalopod “propodium,” the four ventral ones “mesopodium,” the two tentacles “metapodium,” the funnel “epipodium,” adds nothing to the true knowledge of cephalopodous structure, but is a retrograde step, analogous to many of those made by De Blainville, which have left only a heap of useless terms, tending to encumber science, until finally swept away into the bin of oblivion.

The figure of the general archetype, or common plan of the Mollusca, *e.g.* in the *Philosophical Transactions* of 1853, pl. v., gives a straight intestine with opposite orifices, the anus being terminal at what would be the caudal end of the body in *Articulata* and *Vertebrata*. But the most common or archetypal characteristic of the intestine in the *Mollusca* is its being bent upon itself, with the anus more or less directed towards, and in proximity with, the mouth.

A straight intestine, with opposite terminal outlets, is more common or archetypal to animals generally; but it is just the reflected deviation from this general animal plan of intestine that particularly typifies the molluscan province. A bent intestine does not imply an excessive development of gut; that of the Ascidian and of the Cephalopod is shorter proportionally to the body than is the straight gut of the articulate worm or Crustacean.

Any one who may dissect the common cuttle-fish (*Sepia*), or squid (*Loligo*), will appreciate the remark, that it is not because of any excessive development that the gut is bent and the anus directed towards the mouth; it must have been more developed in length to reach the caudal end of the body. But such disposition is not typical of the *Mollusca* generally.

When the archetype of a group of animals is proposed to show or embody “all the organs and parts which are found in the group, in such a relative position as they would have if none had attained an excessive development,” the student requires the standard according to which the “excess” is to be judged. If the proposer of the archetype has no standard to give, his definition has no value.

Another retrograde step in quest of a sound knowledge of the *Mollusca* has been the borrowing of well-defined terms, previously restricted to exemplify the vertebrate and articulate archetypes, and their application to illustrate the proposed molluscan one. Thus, supposing the alimentary canal, from the mouth to the bend of the intestine, to indi-

cate the division of the body into a part *above* and a part *below* such alimentary canal in the slug or snail creeping on level ground, that part in which the functionally most important mass of the nervous system is developed—the superœsophageal brain or ganglionic mass, which, by its connection with the optic, gustatory, and sometimes acoustic nerves, bears the closest analogy with the fish’s brain—has been proposed to be called the “hæmal” side of the slug, and the opposite or under part the “neural” one.

No doubt the upper part of a slug, in which the eyes and feelers, or special organs of exploration, together with the part most like, in function, the pros- and mes-encephalon of fishes, may not be strictly homologous with the dorsal or neural surface of the fish. Such surface in the slug bears a different relation to the vent, the breathing organ, the heart, and, whilst embryonic, to the vitellicle or *vesicula umbilicalis*. But in animals developed on plans so different as the vertebrate and the molluscan, it may be doubtful whether strict homology can be predicated of any organ or part of the body in the two provinces.

What we call *cor*, the “heart,” of a snail, is similar in some degree to that of the fish; it has a similar muscular and valvular bilocular structure, and in both it serves for the propulsion of blood. But in the snail the auricle receives the blood from the breathing organ (lungs), and the ventricle propels it over the body; whilst in the fish the auricle receives the blood from the body generally, and the ventricle propels it to the breathing organ (gills). The parts are to a certain extent “analogous organs,” and have thereby received the same name, “heart.” The circumstances attending the development of the heart, respectively, in the Mollusk and Fish, equally forbid our regarding such heart as strictly “homologous” in the two types. If such homology had existed in nature, there would then be reason in the assertion, that because the heart is situated on the upper or “brain” side of the snail, instead of on the lower or “belly” side of the body, as in the fish, that therefore such upper side in the snail is the true “hæmal” side, and that the snail is as a vertebrate with its “hæmal” or “belly” side upwards.

But the heart of the snail is not the same organ, in the homological sense, as the heart of the fish; it does not therefore determine the same side of the body. It might be less inaccurate to regard it as homologous with the pulsating lymphatic heart which is situated on the dorsal side of the vertebral column in some fishes and batrachians.

An equally retrograde step, as breeding confusion by false analogies and by forced and arbitrary double applications of previously well-defined and well-understood terms, is that proposition which would borrow those of “abdomen” and “post-abdomen” from the articulate archetypal nomenclature, and apply them to parts of the diagrams illustrative of the archetype of the Mollusca.

In the Essay alluded to, the “abdomen” of the Mollusk is defined as “that portion of the hæmal” (meaning *dorsal*) “region which lies in front of the anus:” to that which lies behind it the term “post-abdomen” is applied. Let the student cut off so much of a squid or cuttle as lies behind the anus, and perform the same operation, on a whelk; let him then compare the parts which will be included in so much of the common visceral cavity as he will in each case have removed. When he finds that in both he has brought away the stomach, the liver, the heart, the chief generative glands, &c., then let him endeavour to decipher the sense of the proposition, that in the Cephalopod “the intestine has a *neural* flexure in consequence of the development of an abdomen;” whilst in the pectini-branchiate Gastropod “the intestine has a *hæmal* flexure in consequence of the development of a ‘post-abdomen.’” If he be successful in comprehending the agreement between these propositions and the nature of the things treated of,

Introduc-
tion.

Introduction.

he may better appreciate than the present writer such modes of illustrating the molluscan archetype.

Were the position of the vent homologically the same in all Mollusks, or even in all Gastropods, then that orifice would truly define two regions of the body, and the part in front of it might need one name and that behind it another. But when so extremely variable a part of the surface as that in relation with the anal end of the intestine, in a Mollusk, is assumed as a determinate basis for the enunciation of archetypal or homological propositions, the warmest aspirant for the progress of philosophical anatomy must doubt whether it has been made in the right direction by such guidance.

In the actual state of Zoology and Comparative Anatomy the same terms are, without doubt, applied to different things in different provinces of the animal kingdom; but those terms are not such as have been rigorously defined for a special or technical signification. Thus we speak of the wings of insects and the wings of birds, and of the legs of insects as of quadrupeds,—knowing all the while that the wings of the beetle are not homologous with those of the blackbird, any more than its hind legs are homologous with those of a horse.

Severe logic would call for distinct names for things so different in their structure and development; but one may ask, Will it be more successful than it has been in other matters where it is opposed to common sense? There is a wise moderation that knows how to avoid the greater evil, by drawing a line beyond which precision of terms would be pedantic purism.

The back of a beetle may not possess all the relations to the organs within, which the back of a mole does; but its analogical similarity, like that between the wing of the beetle and the wing of the bird, will insure the permanence of the corresponding term.

So also with regard to the "foot" and "belly" of the Gastropod. If indeed anatomy could demonstrate intelligibly and satisfactorily to its cultivators the part in a snail which was truly homologous with the ventral surface, or with the foot of a vertebrate, we should be bound to restrict those terms to the so demonstrated homologous part. But in the absence of such demonstrations, science in no degree halts through the application of the same general terms, in a few instances, to parts which have a general and patent analogy, though not a strict homology, in different provinces of the animal kingdom.

In the present article the end of the body of the Mollusk, at or near which the mouth opens, is the "fore" or "anterior end;" the opposite is the "hind" or "posterior end." Where the nervous system is reduced to one ganglion, its position in regard to the alimentary canal indicates the *lower* or *ventral* surface of that canal and of the corresponding side of the body; where another ganglion, in connection with antennal and optic nerves, is developed, it is on or near the opposite side of the alimentary canal to that occupied by the homologue of the first or solitary ganglion, and such superadded—usually called "superesophageal" or "cerebral"—ganglion marks the *upper* or *dorsal* surface of the alimentary canal, and of the corresponding side of the body.

The "abdomen" is the common cavity of the body which includes the stomach, intestine, liver, and generative gland; and is distinct from the respiratory cavity, which is usually more or less completely partitioned off from the abdomen.

Special homologies can be determined throughout the molluscan province in regard to the principal centres of the nervous system, to the mouth, to the alimentary canal and vent, to the liver, and some other glands. But it is

Introduction.

not so certain that other parts bearing the same name in the molluscan province are truly answerable. The *branchiæ* of the ship-worm (*Teredo*), for example, are analogous in function, but may not be strictly homologous with the *branchiæ* of the whelk or cuttle-fish; neither can the breathing-tube or "siphon" of the *Teredo* be proved to be the same part homologically with the siphon of the whelk or the funnel of the squid. There is perhaps more ground for inferring that the muscular mass developed from the under or ventral part of the abdomen in most Bivalves is homologous with, as well as analogous to, the muscular part which bears the same name, "foot," in Gastropods.

But whatever doubt may linger regarding the precise homology of the "foot" of a Bivalve and that of an Univalve Mollusk, there can be none respecting the homology of the foot within the limits of the same class. We may trace it as essentially the same part from species to species, from its most rudimental to its most developed state, and under every modification of form, throughout the acephalous or lamellibranchiate Bivalves; and the like with regard to the foot throughout all its modifications in the encephalous Gasteropoda and Pteropoda.

With respect to the Cephalopoda, the chief muscular part of the body forms a conical sheath, containing the retractile mouth or buccal mass, and its more immediate appendages. The inner surface of the sheath is smooth; the outer one gives origin to many parts or processes. When it is found that, in the Gastropods, the acoustic nerves are given off from superesophageal ganglia in one order (*Heteropoda*), and from subesophageal ganglia in another (*Pulmonata*), the homology of any of the cephalic muscular developments of the Cephalopods with the foot, or part of the foot, of the Gastropods, will not be established by a similarity in the origin of their nerves; but there will be no misgiving as to the cephalic sheath and its appendages being homologous parts within the limits of the cephalopodous class.

The more special definitions of such homology is a legitimate and useful subject of research. When, in reference to the numerous sheathed tentacula which project from the muscular cephalic cone of the nautilus, it is suggested that the sheath is a much-developed sucker (*acetabulum*), and that the tentacle is the homologue of the caruncle of the sucker on the arms of the dibranchiate Cephalopod, one mode of expressing a sense of the homology of the parts throughout the cephalopodous class is given. According to this view, the anterior circumference of the oral sheath in the nautilus represents four of the eight arms developed therefrom in the cuttle-fish, the four other arms being represented by the four groups of tentacula which are included within the oral sheath in the nautilus.¹

To this view, while admitting that the oral sheath and its appendages are homologous parts in all Cephalopods, it has been objected² that the origin and connection of the inner groups of tentacula in the nautilus correspond better with those of the two long superadded tentacula than with any of the eight ordinary arms in the cuttle-fish, and that each tentacle corresponds, in its complex organization and in the special modification of its inner surface, rather with an entire arm of the dibranchiate Cephalopod than with the caruncle of one of its suckers. According to this view, the more numerous, though comparatively small, tentacles of the nautilus illustrate, in comparison with the fewer and larger tentacles or arms of the dibranchiate Cephalopod, the principle of vegetative repetition. The reduction of the cephalic appendages in number as the Mollusk rises in the scale of the class, their increase in size, and their per-

Introduc-
tion.

fection as prehensile instruments through the superadded suckers, are phenomena which usually attend the march of development.

The pair of fin-like musculo-dermal organs developed from the sides of the body in *Sepiolo* are analogous to those in *Pneumodermos*; and if homology could be predicated of musculo-dermal developments in the two classes, the fins of the *Sepiolo*, rather than the funnel, would so answer to the fins of the Pteropod. The disc beneath the part of the abdominal integument supporting and inclosing the shell in *Spirula* would seem, in like manner, to be more homologous than the cephalic arms with the ventral disc called "foot" in the *Carinaria*. The derivation of acoustic nerves from the subcesophageal part of the brain inclosed in the cartilaginous skull of the cuttle-fish is as little proof of the homology of such part with the pedal ganglion of a Gastropod as with the supercesophageal ganglion of a Heteropod. No homology will stand or carry conviction, the predication of which involves a suppression or a forced explaining away of opposing facts.

If the homology of the muscular cephalic cone and its appendages in Cephalopods with the muscular ventral disc of Gastropods, cannot therefore be demonstrated; and if the predication of special homologies can only be safely and intelligibly made within the limits of the class, not extended from one molluscan class to another, to the degree in which homologous parts can be traced in the Vertebrata, it is owing to the very nature of the classes of the *Mollusca*. They are more distinct from one another than are the classes of the *Vertebrata*; they exhibit more different, more strongly marked, modifications of the molluscan organization. Above all, differences of structure in the *Mollusca*, and especially the developments of dermo-muscular parts, are, in a much greater degree than in the *Vertebrata*, subordinated to the principle of the conditions of existence, of the reciprocal convenience of parts, of their fitness for the mode and medium of life of the molluscan animal; in a word, are more obedient to teleological than to homological laws.

Every history has its retrogressive as well as its progressive phases; the former have necessitated the foregoing comments.

In resuming the brief account of the real advance of Malacology in recent times, mention ought first to be made of the valuable and beautiful illustrations of the forms, colours, and structure of the new and rare *Mollusca* collected by the scientific naturalists Péron and Lesueur,¹ Quoy and Gaimard,² Eydoux and Souleyet,³ respectively attached to the circumnavigatory voyages instituted by the French government under Baudin, D'Urville, Freycinet, and Vaillant. Their example has been ably followed by Messrs Adams and L. Reeve in the *Mollusca of the Voyage of H.M.S. Samarang*, 4to, 1848-1850.

The figures of the molluscan animals given in these and other original works have been accurately copied, and published in a most useful compendium, in 4 vols. 8vo, by Mrs Gray,⁴ the accomplished wife of the learned and experienced Keeper of the Zoology in the British Museum.

Baron Férussac has enriched Malacology with a beautiful work in folio, with coloured plates, entitled *Mollusques*

Terrestres et Fluviales, of which the last published part, by the Baron, in conjunction with M. Alcide D'Orbigny, treats of the Cephalopods.

Signor Verany⁵ has commenced a splendid work, worthy to be regarded as a continuation of that by Férussac and D'Orbigny, on the Mediterranean *Mollusca*. The first part includes upwards of forty plates of Cephalopods, carefully coloured after the living or recently caught animals.

A work of equal beauty and merit on British Nudi-branchiata, by MM. Alder and Hancock, has been published by the Ray Society.

Our accomplished countryman, W. J. Broderip, Esq., F.R.S., lately retired from his arduous duties as police magistrate at Westminster, has taken a praiseworthy share in the advancement of his favourite science, by devoting his scanty leisure to an extensive series of most exact and classical descriptions of new species of Mollusca and their shells, chiefly collected by Mr H. Cumming, and published in the *Transactions and Proceedings of the Zoological Society of London*. His purse was as liberally opened to secure the rarest specimens of shells brought to the port of London, up to the period when his well-known and most instructive collection was purchased by the British Museum. The several valuable articles on Malacology and Conchology in the *Penny Cyclopædia* are also from the pen of Mr Broderip.

The names of James de C. Sowerby, and of George B. Sowerby, will always be favourably associated with the progress of the molluscan department of natural history. Besides numerous monographs by these authors, the serial works, entitled *The Genera of Recent and Fossil Shells*, the *Species Conchyliorum*, the *Mineral Conchology of Great Britain*, the *Malacological and Conchological Magazine*, and the *Conchological Illustrations*, are indispensable to whoever may devote himself to the study and collection of Mollusca and their shells.

M. L. C. Kiener has beautifully illustrated the conchological treasures of Lamarck and of M. Delessert in his *Species Général et Iconographie des Coquilles Vivantes*. Mr Lovell Reeve has performed a similar desirable work in regard to rarities in English conchological collections, and to Conchology in general, in his *Conchologia Systematica*, *Conchologia Iconica*, and *Elements of Conchology*. He is also the author of numerous valuable monographs on subjects of the molluscan province.

The intimate structure of shell has been elaborately and extensively illustrated by Dr Carpenter,⁶ Mr Bowerbank,⁷ and Professor Quekett.⁸

Professor Agassiz has, with his characteristic originality, lent valuable aid to the study of recent and fossil shells by his *Mémoire sur les Moules de Mollusques, Vivans et Fossiles*, in which the markings of the interior of shells are instructively displayed. The *Etudes Critiques sur les Mollusques Fossiles*, by the same author, will be found most useful to whoever may be engaged in the elucidation of Geology by Conchology.

The study of the collection of Mollusca and their shells in the British Museum is now greatly facilitated by the catalogues of that department which have been drawn up or edited by Dr J. E. Gray, F.R.S.⁹

Introduc-
tion.

The more intimate knowledge of the nature and affinities of the Mollusca has of late years been signally promoted by the series of researches on the embryology or development of those animals, more especially those by Rathké,¹ Carus,² Sars,³ Dumortier,⁴ Van Beneden,⁵ Milne Edwards,⁶ Lovén,⁷ Windischman,⁸ Koren and Danielssen,⁹ Gegenbaur,¹⁰ Schmidt,¹¹ Vogt,¹² and Quatrefages.¹³

The knowledge of the varying forms of the living Mollusks, of their habits and powers, has been increased, and is likely to be materially advanced, by the rapidly extending practice of preserving them in confined spaces of sea or fresh water. Poli, Montagu, and before them probably other lovers of nature, resident near the sea, availed themselves of large vessels to keep alive, in frequently renewed sea-water, the marine animals in the study of which they were interested. But to Madame Jeanette Power (née de Villepreux), according to the testimony of Professor Carmelo Maravigna, in the *Journal du Cabinet Littéraire de l'Academia Giénia*, of Catania, for December 1834, ought to be attributed, if to any one individual, the invention and systematic application of the receptacles now called Aquaria, to the study of marine, and principally of molluscous animals.

Madame Power invented three kinds: one of glass, for preserving and studying living Mollusca in a room; another, also of glass, for small Mollusks, protected by an external cage of bars, in which they could be kept submerged in the sea, and withdrawn at will for inspection; and a third kind of cage for larger Mollusks, which could be sunk and anchored at a given depth in the sea, and raised, when required, for the purpose of observation and experiment. With these different kinds of molluscous menageries, of which the first answers to our present improved and enlarged aquaria, Madame Power carried on her observations and experiments from the year 1832 to 1842 at Messina in Sicily.

She determined the question of the true relation of the *Argonauta*, or Paper Nautilus, to the delicate boat-like shell which it inhabits. She first showed that the so-called "sails" were normally applied over the exterior of the shell, and proved experimentally that they were the organs which formed and repaired the shell.¹⁴ She proved that the *Bulla lignaria* preyed upon, and by its strong gizzard ground down and digested, the *Dentalium entale*. She described the curious manœuvres by which the *Astropecten aurantiacus* seized and conveyed to its mouth and stomach small *Naticæ*. And many other interesting facts were brought to light by this persevering and ingenious observer, through the application of the "Gabioline alla Power,"¹⁵ as her aquaria were termed by the Giénian Academy, some years before the practice of so studying aquatic animals was introduced and diffused in this country.

The scale on which our improved manufactures of plate-

glass have enabled the Zoological Society of London to exhibit living specimens of rare and beautiful marine and fresh-water animals, has struck with admiration the thousands who have witnessed them in the gardens of the Regent's Park.

The management of such aquaria is ably treated of by Mr Warington in the *Annals of Natural History* for 1855, and the instruction and amusement to be derived from them have been illustrated in a most agreeable and interesting style, in popular works, by Messrs Gosse and Sowerby.

The series of works from the establishment of Mr V. Voorst, illustrative of the Fauna of Great Britain, has been enriched by most valuable volumes on the British *Mollusca* by Professor E. Forbes and Mr Hanley.

Dr Johnston¹⁶ and Mr Woodward¹⁷ have compiled most instructive elementary works on general Malacology; both characterized, and the latter more especially, by careful and original research.

Of the illustrations of particular groups of Mollusca in circumscribed localities, those devoted to the fresh-water family *Naiades*, and especially to the genus *Unio*, of the North American rivers, by Mr Isaac Lea, possess the highest value.

Few individuals have contributed so much to the progress of Malacology, since the demise of Cuvier, as Mr Hugh Cuming, F.L.S. His famous collection of shells is known throughout Europe: it contained in 1848 upwards of 19,000 species and well-marked varieties of shells, represented by about 60,000 specimens, which are not only entire, but perfect of their kind, as respects form, texture, colour, and other characters that give the shell value in the eyes of the collector. The mode in which Mr Cuming has accumulated this surpassingly rich illustration of Conchology is as rare and exemplary as the result is marvellous, considered as the work of one individual. Not restricting his pursuit of shells to the shops of the commercial naturalist, the stores of the curiosity-mongers of our seaports, or the casual opportunities of obtaining varieties by purchase, he has devoted more than thirty years of his life in arduous and perilous personal exertions,—dredging, diving, wading, wandering, under the equator, and thence to the temperate zones, both north and south,—in the Atlantic, in the Pacific, in the Indian Ocean, and in the islands of its rich Archipelago,—in the labour of collecting from their native seas, shores, lakes, rivers, and forests, the marine, fluviatile, and terrestrial Mollusks, 60,000 of whose shelly skeletons, external and internal, are accumulated in orderly series in the cabinets which now test the strength of the floors of his house in Gower Street, London.

The result of this personal capture of the chief bulk of his collection is, that he has been enabled to assign to each

Intro-
duction.

shell, not only its country or "habitat" in the ordinary zoological sense, but all the circumstances in which it lived and was developed. If a land-shell, *e.g.*, its favourite rock, or herb, or tree; if a water-shell, the kind of water; and if marine, the habitual depth, and the nature of the sea-bottom at which the Mollusk resided, the rock that it bored, and the animals, the weeds, or other substances it devoured. The value of every shell, in other collections, to which this information applied, became thus greatly enhanced. The importance of these particulars every naturalist and geologist will appreciate on account of the insight that they afford, not only into the economy of living Mollusks, but into the habits and habitats of the fossil shells of the same or allied species; and perhaps one of the most striking points in the estimate of the scientific value of an extensive collection like Mr Cuming's, arises out of its relation, as an indispensable instrument to the determination of fossil shells, to the present active pursuit of Geology.

From the period when the Atlantic, American, and Polynesian departments of the Cumingian collection reached England in 1831, comparative anatomists, malacologists, and conchologists have found subjects, without intermission, for their investigations and descriptions. The organization of the parasitic *Stylifer*, of *Spirula*, *Calyptraea*, *Lithedaphus*, *Clavagella*, and other rare Mollusks, was brought to light through the specimens which Mr Cuming had preserved in spirits. Almost every part of the *Transactions*, and every number of the *Proceedings of the Zoological Society of London*, since the year 1832, contain the descriptions, by Broderip, Sowerby, and Owen, of the novelties liberally submitted to those naturalists by Mr Cuming. And such novelties were far from being exhausted when Mr Cuming, having undertaken a third exploring voyage, returned in 1840 from Manilla, stored with the conchological riches of the Indian Ocean, which have subsequently kept in activity the eyes and pens of Broderip,¹ Sowerby,² Pfeiffer,³ Lovell Reeve,⁴ Adams,⁵ Dunker,⁶ and Philippi.⁷

Of the rare or unique species thus made known to science, Mr Cuming is the possessor, in most instances, of many individuals; and as "dead" shells, or those found without the animals, are strictly excluded from his cabinet, his stores of unique and beautiful specimens give him the command, so to speak, of all the conchological cabinets of Europe. In his annual visits to the Continent, Mr Cuming carries with him the duplicates of his rarities, representing species with the sight of which the eyes of foreign naturalists are gladdened for the first time. They open to him their treasures in return, and from most of the collections—national and private—of Europe Mr Cuming has borne away rare species he did not before possess, in exchange for the still rarer shells which his abundance has enabled him to offer in exchange without detriment to his own rich stores.

His liberality in opening those stores to the student of Conchology equals the enterprise and intelligence with which they have been brought together; and the Cumingian collection is likely long to remain the most important and instructive in Europe for the advancement of the science of the Mollusca.

Mr Van Voorst has brought out, with his usual excel-

lence of type, and more than his usual beauty and costliness of illustration, so much of the *Genera of Recent Mollusca*, by H. and A. Adams, as relates to Cephalopods and Univalves generally, including descriptions of 680 genera and 437 sub-genera; the number of species average nearly 12 to each genus and sub-genus, and altogether exceeds 13,000. The first part of this work was published January 1, 1853.

A considerable proportion of these species are represented by specimens in the Cumingian collection; about half the number are in the British Museum. Besides the shell of each genus, the operculum, when known, is given, and many figures of the living animals have been selected from the best original works.

The classification adopted in this work does not offer any modification based upon original appreciation of structure and affinities overlooked by preceding authors. Inasmuch as the proposed changes are chiefly those of names, and where otherwise, are opposed to deductions from the anatomy of the animals, this part of the work is a retrograde step. Thus the class *Cephalopoda* is divided into the orders—*Octopoda*, *Decapoda*, and *Polypoda*. Now, besides the inconvenience of the same terminology for a class and its orders, we have here a virtual affirmation that the difference of structure between the Poulp (*Octopus*) and the Calamary (*Loligo*) is not less important than that between the *Octopus* or *Loligo* and the *Nautilus*. By the proposed foundation of the orders of the *Cephalopoda* in 1832 on characters of the respiratory system, Professor Owen sought to harmonize the divisions of the highest class with that of the other classes of Mollusca.⁸ The term *Polypoda*, moreover, is that which has been given by Gistel and Aristotle, *e.g.*, to the dibranchiate Cephalopods, or to particular families of them.

In the sale-catalogue of the Yoldi collection of shells by M. Otto Mörch, names that had been applied by old and obscure writers to shells prior to the imposition of generic names on the founding of the Linnæan binomial system, are added, inclosed in brackets, after those names by which the objects are intelligible to Conchologists generally. The Messrs Adams have disfigured their work by the substitution of these justly and practically obsolete terms for many of the well-established generic names applied since the Linnæan system has been in use.

As it may aid in explaining and diffusing the principles upon which the stability of conchological nomenclature is attempted to be preserved by the more judicious cultivators of Zoology, the following list of names offered by the authors of the *Genera of Recent Mollusca*, as substitutes for the accepted names, is appended, together with the comments of a judicious critic, in which the author of the present article entirely coincides:—

Names in use.	Names proposed by Messrs Adams.
<i>Hyalea</i> , Lam. 1799.....	<i>Cavolina</i> , "Gicni" (not of Bruguière, 1792).
<i>Cleodora</i> , Péron, 1810.....	<i>Clio</i> , "Browne" (not of Linn., Müll., Fabr., Brug., Cuv., Lam., Desh., or any other conchologist of note).
<i>Cresetis</i> , Rang, 1828.....	<i>Styliola</i> , Lesueur (teste Blainville).
<i>Cuvieria</i> , Rang, 1827.....	<i>Triptera</i> , Q. & G. 1824. ⁹
<i>Clio</i> , Linn. 1757.....	<i>Clione</i> , Pallas, 1774.

¹ Descriptions of Shells collected by H. Cuming, Esq., in the Philippine Islands, *Zool. Proc.*, 1840, pp. 83, 94, 119, 155, 180; *Ibid.*, 1841, pp. 22, 34, 36, 44, &c.

² *Ibid.*, 1840, pp. 87, 96, 116, 135, 167; 1841, pp. 1, 17, 19, 24, 39.

³ Descriptions of 40 new species of *Haliotes*, collected by H. Cuming, Esq., *Zool. Proc.*, 1846, p. 53; Descriptions of 54 new species of *Mangelia*, collected by do., *ibid.*, p. 59.

⁴ Descriptions of new species of Shells, collected by H. Cuming, Esq., *Zool. Proc.*, 1849, p. 169.

⁵ Diagnoses specierum novarum generis *Planorbis* Collectionis Cumingianæ, *Zool. Proc.*, 1848, p. 40.

⁶ Descriptions Naticarum quarundam novarum ex Collectione Cumingiana, *Zool. Proc.*, 1851, p. 233. The notes are limited to a few references to the Cumingian memoirs by the above-cited Malacologists, as being sufficient to indicate the richness of the new materials collected by Mr Cuming.

⁷ This name was given to an imperfect and misunderstood specimen. In the same plate and in the same page, the authors figured and described the perfect *Cuvieria* under the name of *Cleodora obtusa*, showing they had no intention of founding a genus (in *Triptera*) equivalent to *Cuvieria*.

⁸ *Memoir of the Pearly Nautilus*, 4to, 1832.

Introduc- tion.	Names in use.	Names proposed by Messrs Adams.
	<i>Melongenæ</i> , Sch. 1817.....	<i>Cassidulus</i> , Humph. (not Lam., Fér., or Latr.)

	<i>Auricula</i> , Lam. 1799.....	<i>Ellobium</i> , Bolten (<i>Auris-Mida</i> , Kl.)

"The names thus introduced by the authors are of three kinds:—Some are taken from works published before the time of Linnæus; others were never characterized, and come under the denomination of 'MS. names;' while a few were published under peculiar circumstances, so as to escape observation, and have become obsolete.

"With respect to pre-Linnæan names it is unnecessary here to advocate the practice adopted by all the best naturalists; we will only hint the extreme inconvenience of a nomenclature ever liable to change, and ever receding into the obscurity of olden literature. If the names of Klein are to be adopted, why not those of Langius and Davila, and Breynius, Bonanni, and Petiver? And if some of Klein's names are used, why not all?

"The question of manuscript names is more difficult, owing to wilfulness of authors. One says it is sufficient to write a new generic name on a tablet and shut it up in his cabinet,—it is to be *dated* from that act.² Another distinguished professor of an English university holds that to inscribe the name on a *museum* specimen is a sufficient act of publication, leaving the determination of the date to the memory of the curator. Some consider the insertion of a new generic name in a catalogue, without a word of description, without even a specific name attached, is sufficient to give 'priority.' Others, more modestly, admit the desirableness of the addition of a known specific name, but do not consider any description necessary; any one that pleases may find out the characters of the new genus, and if it has none, it is but one more name added to the synonymy.

"The genera of Humphrey, quoted in the foregoing list, appeared in the *Museum Calonneanum*, a catalogue published anonymously in the year 1797, and containing names only, without definitions. Names attributed to Bolten are also supposed to be taken from a catalogue. We have found the name 'Gevers' placed as the authority for Meuschen's names in the *Mus. Geverianum*, and 'Berlin' for Link's names in the Berlin Museum. But who wrote the *Museum Boltenianum*?

"The Linnæan code, of which Herrmannsen gives an excellent digest, and the rules of the British Association, require that names should be really published, and accompanied by a description sufficient to identify the object and justify the imposition of the new term."

The adoption of generic and specific names in the following pages will be governed by those rules.

PROVINCE MOLLUSCA, Cuvier.

(*Heterogangliata*, Owen.)

CLASS I.—TUNICATA, Lam.

(*Acephales sans Coquilles*, Cuvier.)

Acephalous Mollusoids inclosed in an elastic uncalcified tunic, perforated by two apertures, and composed of a peculiar substance resembling the "cellulose" of plants, in having no nitrogen, but only carbon and hydrogen.³

ORDER I.—SACCOBRANCHIATA,⁴ Owen.

(*Les Ascidies* and *Les Aggrégés*, Cuv.)

Mantle united to the tunic at the two orifices; elsewhere commonly more or less detached. Branchia, a dilated, ciliated, vascular sac, with commonly a tentaculigerous orifice.

Tribe 1.—AGGREGATA, Cuv.

The aggregate, associated, or compound Ascidians (fig. 5) are all of small size. Their organization is essentially like that of the larger solitary species, but the viscera are somewhat differently disposed,—the cavity of the body is in most longer and narrower, the entire animal viewed singly being more vermiform. In their natural organic association they are arranged in different modes, and under different forms characterizing different families. Some, as the beautiful *Diazona*, diverge, like the petals of a compound flower, from a common base; others, as the *Botryllus*, are arranged in circles round a common central aper-

¹ We cannot find any such "genus" in Guettard's *Memoirs*, but according to Blainville it was merely a name given to a miscellaneous assemblage, including *Vermæus*, *Scalaria*, *Magilus*, &c.

² Schmidt, *Zur vergleichenden Physiologie der Wirbellosen Thiere*, 8vo, 1845.

³ Introduction to D'Orbigny's *Prodrome de Paléontologie*.

⁴ Greek, signifying "sack-shaped gills."

Tunicata. ture, beneath which the anal extremity of the intestine of each individual terminates; whilst many of these circles of individuals are aggregated together, and enveloped in a common cellulose tunic. The substance of this in some species, *e.g.* *Septodinium*, is crowded with calcareous granules; in others, *e.g.* *Botryllus*, it exhibits distinct fibres.

Some of the compound Ascidiæ are ramified (as, *e.g.*, *Perophora*, fig. 5), and their tunics are so transparent as to permit the movements of the internal organs to be studied in the living animal. The individuals of this genus are connected only by tubular prolongations of the common tunic, and are rather "social" than "compound" animals. In these a very singular condition of the circulating system has been detected.¹ The blood moves backwards and forwards, to and from the heart, in the same vessels, as it was supposed to ebb and flow in the human veins before Harvey's great discovery. The oscillation of the currents is not constant and regular; the blood is received from the vessel at one end of the heart (fig. 5, *n*), and propelled by a contractile wave into the vessel at the opposite end. After a true circulation has gone on in this course for a certain period, a change is observed in the course of the peristaltic contractions of the heart; the blood for an instant stagnates in the sinuses and vessels, and then the wave travels in the opposite direction; the heart drives the blood into the vessel from which it had before received it, and the course of the circulation is reversed. In the compound Ascidiæ the vascular systems of the different individuals anastomose freely with each other. The veins are chiefly in the condition of large lacunar sinuses. The heart and vessels circulate blood, not water: if the vessels, as some contend, had no proper tunics (and their transparency in the living Ascidiæ renders them, in most of the sinuses, invisible), the sea-water which freely passes from the branchial to the muscular cavities would flow into the so-called intervisceral lacunæ were they merely such as they seem.

At first sight it is difficult to conceive how the fixed and compound Ascidiæ can multiply their race in situations at a distance from that which they themselves occupy.

This difficulty has been removed by MM. Audouin and Milne Edwards, who observed that the young of the compound Ascidiæ were not only at their origin solitary and free, but possessed the power of swimming rapidly by the aid of the undulatory movements of a long tail (fig. 5, *C*). They were seen occasionally to attach themselves to the side of the vessel of sea-water containing them, and then to recommence their course, as if to seek a more suitable point of attachment. After two days of free and locomotive life, they finally fixed themselves, and, when detached, remained motionless.

Similar locomotive phenomena are now known to be common to the embryo of many of the lower sedentary animals. In regard to the Ascidiæ, it has been confirmed by Sars in the *Botrylli* of the coast of Norway,² by Sir John Graham Dalyell in a solitary Ascidian of the Firth of Forth; and the embryogeny of the *Cynthia Ampulla* has been well followed out by Professor Van Beneden.³

In the genera *Polyclinum* and *Amaroucium*, amongst the compound Ascidiæ, Milne Edwards has observed that the ovum, whilst still included in the ovarian mass, consists of the small central germinal vesicle, of a granular vitellus, and a vitelline membrane. In the progress of the ovum to the cloacal cavity the yolk acquires a deep yellow colour, the germinal vesicle disappears, and in its place there is a nebulous speck upon the surface of the yolk. The extremity of the

yolk opposite to the caudal attachment develops a series of cylindrical productions. Three of them have expanded extremities which increase in length; whilst the other processes diminish, and finally disappear. A spiral filament is continued from the membrane of the vitellus down the centre of the tail. In this state the embryo escapes from the ovum, generally while in the cloaca of the parent, but sometimes after the egg has been expelled from the common central outlet.

The young animal immediately unfolds its tail, and begins to swim like the tadpole of the frog, which it so much resembles in form. The three clavate cephalic processes are the organs by which Milne Edwards believes it effects its final adhesion and settlement. When this has taken place, the tail shrinks, and is usually detached by progressively increasing contraction at its base,—a kind of spontaneous fission.

The sessile and adherent trunk now becomes the seat of an active development. The integument is thickened. The germ-mass becomes elongated and divided by a circular constriction into two unequal parts, which severally open a passage, constituting, the one an oral (fig. 5, *g*), the other an anal (fig. 5, *f*) orifice. The subdivided germ-mass, which now begins to be rapidly metamorphosed into the special tissues, also acquires a distinct tunic *b*, which soon separates itself from the thick and gelatinous external integument *a*.

The quadrifid orifice of the branchial sac (fig. 5, *e*) is first formed upon the internal tunic. The contour of the great respiratory pharynx can next be discerned, and the constriction of the sac opposite to the mouth, which indicates the cesophagus (fig. 5, *d*). About the same time may be seen the outline of the anal orifice (fig. 5, *k*) upon the internal integument; then the opaque yellow tunics of the dilated stomach (fig. 5, *i*) and the reflected intestine appear; and below these parts the pulsations of the large transparent vasiform heart (fig. 5, *n*) render that organ conspicuous. Around each external orifice some mammilloid processes (fig. 5, *g'*) bud out, which first lengthen, and afterwards in some species become lost in the thickening integument. The eye-speck continues for some little time, and is situated in the middle of the nervous collar (fig. 5, *k*). At the base of the abdomen the opaline concretionary body appears, to which the heart is subsequently attached, and which is provided with vibratile cilia.

The whole of the viscera included by the smooth integument have been observed to rotate in the cavity formed by the thick gelatinous tunic, to which the visceral mass again becomes attached by the adhesion of the muscular tunic at the branchial and anal orifices, and by the establishment of corresponding orifices in the integument.

Savigny⁴ was of opinion that the ovum of the compound Ascidian contained the germs of all the individuals composing the characteristic groups in the mature aggregate animal, and that their development was simultaneous. In one sense, doubtless, the ovum contains the germs of all the future individuals developed by gemmation, in so far as a portion of the germ-mass is retained unchanged in the body of the first developed individual; but the cell-progeny of the primary germ-cell constituting that germ-mass are not simultaneously developed, nor does any development begin until the first individual is completed, fixed, and nourished by the action of its proper digestive apparatus. Thus stimulated and strengthened, the second mode of reproduction, namely, that by gemmation, is superinduced upon the young Ascidian (fig. 5, *B*), after the foregoing development from the impregnated ovum (fig. 5, *A*). This offers an interesting ana-

⁴ Mémoires sur les Animaux sans Vertèbres, 8vo, Paris, 1816.

Tunicata. logy to the phenomena presented by the polype-larva of the Medusa. The individuals (fig. 5, B) formed by the gemmation of the primary bud of the young Ascidian (fig. 5, A), instead of being detached, are retained, the process of gemmation being regulated so as to produce the characteristic pattern in which the different individuals are grouped in the mature compound animal.

FAMILY I.—BOTRYLLIDÆ.

Body fixed; tunics of many individuals fixed together into a mass, in which the individuals are grouped into systems.

Genus BOTRYLLUS,¹ Gaertner, 1774.—Body of the individual not divided into thorax and abdomen; branchial aperture circular, without rays; social systems numerous, with from six to twenty individuals in each, lying nearly parallel to the periphery of the mass; vent remote from the simple branchial aperture.

Sp. Botryllus violaceus.—Greenish-gray, with dark-blue stars, yellow in the centre round the common orifice. On stones and sea-weed near low-water mark. British.

Genus DIDEMNUM,² Sav.—Thorax and abdomen distinct; branchial aperture with six equal rays or lobes.

Sp. Didemnum candidum.—Gulf of Suez.

Genus DIAZONA,³ Sav.—Compound group sessile, sub-circular, hollow in the middle; individuals arranged in concentric circles; both branchial and anal apertures six-rayed.

Sp. Diazona violacea.—The compound mass resembles an Actinia, and attains a diameter of 6 inches; it is of a beautiful violet colour. Mediterranean.

Genus POLYCLINUM,⁴ Sav.—Divided into thorax or branchial cavity; upper abdomen with the digestive organs, and lower abdomen with the heart and reproductive organs; branchial orifice six-rayed, anal orifice simple.

Sp. Polyclinum constellatum.—Hab. Mauritius.

In the progress of the gemmation by which the compound groups of the foregoing family are formed, a bud is first developed in the form of a small tubercle from the abdominal portion of the internal tunic of the young Botryllid. The tubercle becomes prolonged, retaining an active circulation in its interior, and is accompanied by a corresponding growth of the outer cellulose integument, which becomes clavate. The process then bifurcates; the divisions, in like manner, becoming elongated, expanded, and bifurcated at their extremities.

Soon the outline of an Ascidian is sketched in each of these extremities. The primitive connection with the parent is obliterated; but the young individuals remain united together by their common peduncle according to the law which determines their mode of grouping into systems. By the progressive increase of their outer gelatinous integument they coalesce and form the compound mass.

The procreative force of the germ-mass finally exhausts itself in the formation of the male and female organs, in which that force is again mysteriously renewed, under its two forms of the spermatozoon and the germinal vesicle, by the combination of which the reproductive cycle again begins its course.

FAMILY II.—CLAVELLINIDÆ.

Body fixed; individuals connected by repent tubular prolongations of their common fixed tunics.

Genus CLAVELLINA,⁵ Sav.—Body oblong, erect, pedunculate; tunic transparent; branchial and anal apertures without rays; branchial sac short, not plicated, without papillæ.

Sp. Clavellina borealis, Sav. (*Ascidia clavata*, Pallas. **Tunicata.** *Spicil. Zool.* x., tab. i., fig. 16).—Thoracic region marked with coloured lines. Greenland.

*Genus PEROPHORA*⁶ (discovered by Lister, 1834; so named by Wiegmann).—Body compressed, suborbicular, pedunculated, upon a common repent tubular stem; branchial sac occupying a great part of the body, with a papillose orifice.

Sp. Perophora Listeri (fig. 5).—Shores of Britain.

Tribe 2.—SOLITARIA.

(*Les Ascidies*, Cuv.)

The exterior tunic of the solitary Ascidians (fig. 6, *a*) is a thick gelatinous or coriaceous elastic substance, adhering by its base, or by a long flexible peduncle, to some foreign body, and perforated at the opposite end or at the side by two apertures *h* and *f* (fig. 6). The exterior of this tunic is sometimes rough and warty, the inner surface always smooth and lubricous. Microscopically examined, it consists chiefly of a conglomerate of non-nucleated cells like the parenchyma of *Cacti*. Chemically analysed, 100 parts of the tissue, free from ash and water, gives, of carbon 45.38, hydrogen, 6.47; being the same composition as the "cellulose" of plants.

This non-azotized tissue is traversed by large blood-vessels, and towards its inner surface crystals and nuclei are abundant in the clear homogeneous basis. The lining membrane is composed of a layer of polygonal, nucleated, epithelial cells.

The second tunic *bb* is muscular; it adheres to the outer tunic at the circumference of the two orifices *h*, *f*, and is connected to it by blood-vessels at a few other points; elsewhere it is quite free, and the opposed surfaces of the intervening space between the muscular and elastic tunics have the aspect of a serous cavity. Its fine fasciculi of fibres are remarkably distinct, and are arranged in two layers,—the external circular, the internal longitudinal. The fibres or fasciculi of the outer layer are smaller than those of the inner one, and less regularly disposed.

They describe regular circles around the processes leading to the orifices of the tunic. Other fibres of the outer layer pass transversely from one tube to the other. The longitudinal fasciculi radiate from the two orifices, and decussate each other, winding round the bottom of the sac. Deeper again than this layer there is a splinter surrounding the base of each tube or orifice, from which a third more delicate layer of longitudinal fibres is given off.

Of the two more or less protuberant and stellate apertures in the outer tunic, one (fig. 6, *f*) leads directly into the muscular sac, the other (*h*) into a wide vascular branchial sac (*dd*) contained in the muscular one. The entry to the branchial sac is defended by a circle of short tentacles. A portion of the muscular tunic is dissected from the branchial sac at *c*. The branchial sac is opened, and one-half reflected backwards, showing the inner surface at *dd*: the opposite wall of the sac *d* is dissected away from the alimentary canal *ee*. The inner surface of the sac *dd* is marked by parallel and equidistant transverse lines, the interspaces of which are divided into a series of narrow, vertical, perforated, and richly ciliated compartments; two opposite narrow longitudinal tracts are entire. A groove along that which traverses the larger curvature of the sac leads to the mouth—an orifice (fig. 6, *k*) near the bottom of the branchial sac. This orifice conducts, by a short oesophageal canal, to the stomach *b*; this is an oblong cavity with longitudinal folds. The intestine is disposed in a sigmoid flexure, adheres to the outside of the branchial *d*, and the inside of the muscular sac *b*,

¹ Gr., signifying "a cluster of grapes."

⁴ Gr. for "many cavities."

² Gr., signifying "double couch."

⁵ Gr. for "little staff."

³ Gr., signifying "in circles."

⁶ Gr. for "sack-bearer."

Tunicata. and terminates by a fimbriated anal aperture *n*, near the base of the second or anal orifice of the tunic *f*.

The liver consists of blind follicles produced into tubes which anastomose, surrounding more or less of the intestine as by a network, and ultimately, at least in *Cynthia tuberculata*, communicating with the stomach by a single

aperture, from which a groove is continued towards the cardia.

The heart is a simple, elongated, vasiform muscle, inclosed in a pericardium attached to the branchial sac, continued at either end into a vessel; the ramifications of one being expended chiefly upon the respiratory organ; those of the

Tunicata.

Fig. 6.

Ascidia gelatinosa.

other upon the tunics of the body, or speedily expanding into sinuses surrounding the viscera. According to the direction of the circulating currents, the one trunk-vessel will be an artery, the other a vein, and the circulation itself will be pulmonic or systemic.

The nervous system must be first sought for in the interspace between the two openings of the muscular tunic: there is situated a ganglion (fig. 5, *h*), from which it is not difficult to trace filaments diverging to each aperture of the sac where the circular disposition of the muscular fibres prevails; other branches accompany the longitudinal fibres, and supply the respiratory sac; two contiguous filaments are continued to the cesophageal orifice.

Eight pigmental spots or eye-specks have been detected at the entrance of the respiratory tube, and six, of a deep yellow colour, at the entrance of the anal tube.

In the animal manifesting this organization, which is much richer unquestionably than the amorphous and rugged exterior would seem to promise, the only vital actions obvious to ordinary vision are an occasional ejection of water from the orifices of the tunic by a sudden contraction, succeeded by a slow and gradual expansion of the entire body. Such contractions and expansions, aided by the ciliary currents, and the peristaltic movements of the alimentary, circulating, and secreting tubes, are all the actions which the organic machinery has to perform in the living Ascidian. The respiratory currents of sea-water, with the nutrient molecules in suspension, are introduced by the ciliary action through the branchial orifice *h* (fig. 6) into the pharyngeal respiratory sac *d*, from which the cesophagus *k* selects the appropriate food. The alimentary excretions and the generative products are expelled through the anal outlet *f*; by the contraction of the muscular tunic *b*.

In consequence of the space between this and the outer tunic being closed, that tunic accompanies the muscular tunic in its contraction, through the influence of the surrounding pressure; when the muscle ceases to act, the elasticity of the outer coat begins to restore the contractile sac to its former capacity, and the surrounding water flows into its cavity, either directly or by distending the branchial sac.

We shall find other instances of the economizing of muscular force by the substitution of elasticity as we ascend in the survey of the molluscous organization.

Eysenhardt¹ has observed the act of gemmation in a simple Ascidian. In this, as in the compound kinds, gemmation commences by the development of a small tubercle from the abdominal portion of the internal tunic of the young Ascidian. Some solitary *Ascidia*—e.g., *Cynthia*—according to my observations, are of distinct sex. In the male a generative gland, commonly dendritic in shape, occupies the concavity of the intestinal fold, and sends a short and simple duct to terminate near the anus. In the female of the *Cynthia tuberculata* there are two ramified ovaria; the ovisacs being appended to the branches of a central stem, passing up the side of the rectum, and extending over one side of the branchial sac. In these the ova in different stages of development may be seen. The sexes are distinct in *Doliolum*; but are stated to be united in most solitary Ascidians, as in the compound forms. The impregnated germ-cell multiplies itself at the expense of the yolk, and incloses that substance by a series of secondary cells. As this process goes on, the yolk, so subdivided and assimilated, takes on a granular surface, each granule or tubercle having its hyaline nucleus. By the coalescence of the peripheral layer of these cells an external membrane is formed, on the exterior of which are oil-like globules. An albuminous fluid is now interposed between the chorion of the egg and the germ-mass. A filamentary body next begins to be formed from a part of the exterior germ-cells forming the basis of the test, which body bends over the visceral mass. This body or process progressively elongates, then uncoils itself, liberating the rest of the test with the visceral mass, and becoming a freely-vibrating locomotive caudal appendage, as in the larva of the compound Ascidian (fig. 5, C). After its attachment it becomes metamorphosed and developed into the animal, whose organization is illustrated in fig. 6.

FAMILY ASCIDIADÆ.

Individual solitary, fixed; branchial sac simple or plicate.

¹ Ueber einige merkwürdige Lebenserscheinungen an Ascidien, *Nova Acta Acad. Nat. Curios.*, tom. xi., 1823.

Tunicata.

Genus BOLTENIA, Sav.¹—Body sub-globular, pedunculate; tunic coriaceous; orifices lateral, 4-cleft; branchial sac deeply plicated, with compound tentacles at its orifice.

Sp. *Boltenia reniformis*, M'Leay.—Greenland. This species has been brought up from a depth of 70 fathoms.

Genus CHELYSOMA, Broderip.²—Body depressed, discoidal, sessile; tunic coriaceous, composed of polygonal plates; orifices closed by six triangular valves.

Sp. *Chel. Macleayanum*.—Greenland.

Genus CYNTHIA, Sav.³—Tunic coriaceous, sessile; orifices 4-lobed; branchial sac plaited longitudinally, with a tentaculate orifice.

Sp. *Cynthia papillata*, Sav.; *Cynthia microcosmus*, Cuv.—The latter is esteemed as an article of food in some parts of the Mediterranean.

Genus ASCIDIA.⁴—Body sessile, covered with a coriaceous or gelatinous tunic; branchial orifice 8-lobed, furnished inside with a circle of simple tentacular filaments; anal orifice 6-lobed; branchial sac not plaited, its meshes papillated.

The Ascidiæ vary in length from 1 inch to 5 or 6 inches. The test is pale and semitransparent, the inner tunic orange or crimson, or sometimes marbled with crimson and white; the ocelli are red, or yellow with a central red spot.

Sp. *Asc. gelatinosa* (fig. 6).

ORDER II.—DACTYLOBRANCHIATA,⁵ Ow.

(The character of the order is also that of the single family composing it.)

FAMILY PYROSOMIDÆ.

In one (the commonly occurring) state, many individuals form a compound body, swimming freely, with the tunics fused into a cylindrico-conical mass, in which they have a verticillate arrangement. In each individual the apertures of the external covering are opposite and terminal. The branchial sac with two gills, girt anteriorly by a membranous denticulate ring; open posteriorly. All the species are pelagic.

Genus PYROSOMA,⁶ Péron.—A connecting link between the Ascidiæ and Salpiæ is afforded by certain compound floating gelatinous *Tunicata*, called, from their phosphorescent or luminous property, *Pyrosoma*, the individuals of which are permanently aggregated into a compound organic whole, having a definite form like a flattened cylinder. The common tegumentary mass is toughish and semitransparent. The tubercles with which its exterior is covered consist each of one inhalent end of an individual member of the living group; the opposite exhalent end of the individual opens into the cavity of the cylinder. Besides the common envelope, each individual has a distinct tunic or mantle attached at the oral or branchial orifice, at the anal orifice, and also to the two rounded bodies at the upper part of the branchiæ. The mantle is connected with the envelope by the delicate membrane of the venous sinuses. The branchiæ are two in number, oval in form, with their dorsal borders in contact and attached to the mantle, and their ventral borders separated by a large sinus; their numerous vessels anastomose at right angles, forming a quadrangular network, and the covering tissue is beset with vibratile cilia, which perform vortex-like movements with beautiful harmony and rapidity. The currents so discharged from the individual into the common cavity produce an outflow from the open end of the cylinder, and the re-action impels it slowly with its blunt

end foremost. The œsophagus is curved and of a bright red colour; the stomach is subglobular, yellowish, and opaque; the intestine is short, bent abruptly on itself; the anus directed backwards towards the posterior orifice. The liver is a globular gland, with converging segments; it is attached to the intestinal loop. These viscera are situated posterior to the branchial sac, leaving a free passage to the water, which traverses the cavity. The nerve-ganglion lies upon the anterior end of the branchial sac. The heart is placed at the posterior part of the body, below the visceral mass, which is connected with the mantle by a pedicle near the inner part of the endostyle. There is a long, apparently hollow, filament contained in the dorsal sinus. Savigny figures an ovum, and a part which he supposed to be an oviduct; but the precise condition of the generative organs in the *Pyrosoma* is at present not clearly made out. Savigny, to whom the knowledge of the compound nature of the *Pyrosoma* is due, seems plainly to have observed an embryo, which had already constituted by gemmation four individuals before being excluded. This is the commencement of the cylinder at its smaller and closed end; it appears to be elongated by the like parthenogenetic propagation of successive circles or whirls of Ascidian-like individuals.

Sp. 1. *Pyrosoma atlanticum*, Péron.—Individuals arranged round the cylinder in close whirls. The name was applied to the compound cylinder, under the impression that it was the individual. It is ordinarily from 3 to 7 inches in length, and from 1 to 3 inches in circumference; open at one end, closed and bluntly rounded off at the other.

Syn. *Pyrosoma giganteum*, Lesueur (*Voyage aux Terres Australes*, pl. 30, fig. 1); Savigny (*Mém.*, ii., pl. 4, fig. 7; pl. 22 and 23).

The species is widely distributed over the tropical and warmer seas. Viewed from a ship's deck, they sometimes seem to form vast tracts of luminous matter stretched across the waves; when closely scanned, as the keel ploughs through the mass, it appears to be composed of countless cylinders resembling incandescent iron. Fishes and other contiguous marine animals are made visible by the light of the *Pyrosoma*. It is of a vivid greenish hue, appearing to be emitted in sparks from the individuals in quick succession, beginning at the point touched. In captivity the power gradually fails, and the light excited by a touch or concussion soon fades whilst the animal is in sea-water; but under the stimulus of fresh water it is said to be brightly emitted as long as life remains.

Sp. 2. *Pyrosoma elegans*, Lesueur.—Individuals arranged round the cylindroid in regular circles.

This species is founded on conical cylindroids of a small size, found in the Mediterranean. (The truth and constancy of the characters of this species need confirmation.)

ORDER III.—TÆNIOBRANCHIATA,⁷ Ow.

Mantle adhering throughout to the tunic; orifices opposite, terminal or subterminal without tentacles; branchia riband-shaped; animals pelagic, free, floating; inhaling water by one aperture, expelling it by the other; individuals, in one generation, connected chain-wise; free in the next generation; and so alternately associated and solitary.

FAMILY SALPIDÆ.⁸

The third order of the *Tunicata* includes the Salpiæ, which float in the sea, and are characterized by their transparent elastic outer tunic, which is elongated, compressed,

¹ After Dr Bolten.

⁴ Gr. for "a little skin-bottle."

⁷ Gr. for "riband-gilled."

² Gr. for "tortoise-body."

⁵ Gr., signifying "gills with a ring."

⁸ Gr., *salpe*, a luminous fish.

³ A name of Diana.

⁶ Gr. for "fire-body."

Tunicata. or prismatico-cylindroid, and open at both extremities. The efferent orifice (fig. 7, *d*) is simple and tubular; it can be closed by a sphincter when the outer tunic expands, the water then flowing in by the opposite orifice *c*. This is in the form of a transverse slit, having an upper and a lower lip. The latter is reflected inwards, and forms a semi-lunar valve, allowing the entry and preventing the exit of water; the muscular fibres of the mantle *f*, or membrane lining the cartilaginous tunic *ab*, are arranged in flattened, often subannular, bands *g*; their elementary fibre is striated. The mouth, the stomach *l*, the liver and the heart *o*, are aggregated in a small mass or nucleus near the anterior aperture of the tunic; the intestine *k* extends towards the opposite aperture, and terminates freely at *l* in the common cavity of the mantle. The intestine, in *Salpa gibbosa*, has two cæca which project into the centre of the loop. In *Salpa zonaria* the liver envelopes nearly all the intestinal canal, and consists of a mass of cæcal tubes, with a few small appendages near their free ends. The group of small yellowish nervous ganglia is situated just above the oral attachment of the branchia *n*; near it is often observed a pigment-speck or ocellus. The single narrow plicated riband-shaped branchia *n* extends obliquely lengthwise across the pallial cavity. The heart *o* is elongated, and in some species slightly curved and sacculated; it communicates with a large vessel *m* at each extremity, one of which is ramified principally upon the visceral mass, the other upon the branchia and the muscular tunics. The blood passes into extensive venous sinuses before returning to the heart; its course is oscillatory, as in the Ascidians.

The sexes are distinct in certain individuals of the Salpians, as they are in some of the solitary Ascidians.

The testis is described by Krohn¹ as of an oblong form, single, lodged in the centre of the nucleus in *Salpa maxima*, in which it consists of numerous delicate seminiferous tubes filled with a white fluid, and opening by a short canal into the common cavity of the body. The two oblong bodies *d*, sometimes of a violet colour, attached to the mantle, have been regarded as ovaria; but they are more properly a "proliferous stolon," engendering by independent force, or independently of direct impregnation. Thus Sars maintains that the solitary individuals of the Salpæ are sexless. The germinative tube, in which the chain of young Salpæ are contained, winds round the visceral nucleus, hanging freely by one end in the cavity of the mantle, and being attached by the other end to the back of the nucleus. The Salpæ, thus developed from internal buds, are usually produced in groups, which are successively excluded through an aperture in the tunic opposite the end of the stolon.

The chief conspicuous vital action in the Salpians is the rhythmical contraction and expansion of the body, in which the elasticity of the outer tunic antagonises the muscular contraction of the inner one. During expansion the sea-water enters by the aperture *c*, and is expelled in contraction by the opposite one *d*, its exit by the first aperture being prevented by the valve. The re-action of the jet, which is commonly forced out of a contracted tube, occasions a retrograde movement of the animal. The cur-

rents which successively traverse the interior of the animal renew the oxygenated medium upon the surface of the re-

Tunicata.

Fig. 7.
Salpa pinnata.

spiratory organ, bring the nutrient molecules within the reach of the ciliated sub-spiral labial membrane of the mouth, and expel the excrements and the generative products. Thus, a single act of muscular contraction is made subservient to the performance of the functions of locomotion, nutrition, respiration, excretion, and generation.

The aggregate Salpians quit their gemmiparous parent, associated together in long chains. After floating for a certain time, each individual, as De Chamisso² first discovered, propagates a young one like itself. The solitary *Salpa* propagated by each individual of the chain is the product of an impregnated ovum, and is for a time suspended by a peduncle from the dorsal wall of the visceral cavity of the parent. The development of the individual Salpæ has been studied by Dr Leuckart. The first evidence of differentiation is the formation in the embryonic mass of a closed cavity, from the walls of which the bar-shaped gill is detached, leaving behind it a space, which becomes the cloaca. The alimentary canal simultaneously makes its appearance. At a later period the branchial chamber communicates with the exterior by the branchial and cloacal orifices. In the *Salpa zonaria*, however, as many as three pedunculated young have been found in one parent when liberated. The solitary *Salpa* grows to the size of the grandparent, and then brings forth a social chain of young Salpæ, which, by the exercise of their uniparous generation, again give origin to the solitary and multiparous individuals. "Thus," observes Chamisso, "only the alternate generations resemble each other."

The case is strictly analogous to the generation of the compound Ascidians, of which the solitary young gives origin, by generation, to a connected group, each individual of which again procreates, by impregnated ova, free individuals. Most Salpians are usually luminous by night.

Genus SALPA.—The characters of the family are those also of the type-genus. Syn. *Thalia*, Brown; *Dagyza*, Banks and Solander (Home, *Comparative Anatomy*, vol. ii., pl. lxxi., figs. 2 and 3, engraved from drawings by John Hunter; see Owen's *Physiological Catalogue of the Hunterian Collection*, vol. i., p. 133, 4to); *Biphores*, Cuvier.

Sp. 4. *Salpa gibbosa*, Quoy and Gaimard (*Voyage de l'Astrolabe, Zoologie*, tom. iii., 1835, pp. 559-598, pl. 86-89).—Specimens, Nos. 480, 481, Physiol. Ser., Hunt. Mus., London.

Sp. 5. *Salpa infundibuliformis*, Quoy and Gaim., *ibid.*—Specimens, Nos. 482, 483, Physiol. Ser., Hunt. Mus., Lond.

Sp. 6. *Salpa polycratica*, Forsk.

Genus ANCHINÆA, Eschricht.—This name has been given to small Salpæ, associated in a single row to a gelatinous filament.

Genus DOLIOLUM.—Body cask-shaped, open at the ends; muscular bands six, equidistant; branchiæ in two bands with vertical bars, one on the dorsal, the other on the ventral surface, converging and confluent posteriorly.

Sp. *Doliolum denticulatum*, Quoy and Gaimard.—Only the solitary form of this species has been yet observed.

Genus APPENDICULARIA, Chamisso. (Syn. *Oikopleura*, Mertens; ¹ *Vexillaria*, Müller.)—Body ovoid, with a long appendage from the dorsal surface of the posterior end, making an angle with the axis of the body, and leading to a large cavity with venous sinuses. The branchia is represented by a ciliated pharynx, communicating with the exterior by two short tubes (discovered by Gegenbauer), ciliated where they leave the cavity, and opening immediately on the dorsal surface in front of the base of the appendage.

Sp. *Appendicularia flabellum*, Chamisso.—This species is one-sixth to one-fourth of an inch in length, and has been observed in such numbers as to form cloudy patches of red substance on the surface of the sea. It resembles the larva of the Ascidians; but Mr Huxley states that he observed spermatozoa in some individuals.² No female or aggregated form of *Appendicularia* has yet been seen.

CLASS II.—BRACHIOPODA,³ Cuvier.

The Acephalous Mollusks of this class are deprived, like the Ascidians, of the power of locomotion, and are attached by a peduncle or by the shell to foreign bodies. Their soft tunic or mantle is, as it were, slit open, and consists of two broad membranous expansions, called "lobes," which are covered by two calcareous plates or "valves," applied, one to the dorsal, the other to the ventral surface, so as to inclose and defend all the soft parts of the animal. The breathing organs consist chiefly of vascular ramifications or processes on the inner surface of the pallial lobes, whence the name Pallio-branchiata,⁴ which has been applied to the Brachipods. The viscera are situated at the part of the shell next the hinge or peduncle, and in one order are confined to a small space there. The rest of the interspace of the pallial lobes is almost entirely occupied by two long fringed arms, continued from the sides of the mouth, and disposed wholly or partly in spiral curves. All the species are marine. They may be briefly characterized as follows:—

Body symmetrical, with a dorso-ventral bivalve shell, lined by a closely-adherent mantle of two widely-separated lobes. Oral brachia two, long, fringed, and ciliated, usually more or less spirally disposed.

ORDER I.—ARTHROPOMATA, Ow.⁵

Shell-valves articulated; calcareous; viscera occupying one-third, brachia two-thirds, of the shell-cavity.

FAMILY I.—TEREBRATULIDÆ.⁶

Brachio-
poda.

Shell-structure minutely tubular. Ventral valve (fig. 8, V) with a prominent notched or perforated beak, and two curved hinge-teeth; dorsal valve (fig. 8, D) with a depressed umbo, a cardinal process between the dental sockets, and an internal calcareous, usually looped, appendage *f* supporting the two long bent and spiral brachia *d*, *e*; attached by a short pedicle *n*, or sessile by a part of the ventral valve.

Fig. 8.
Waldheimia flavescens.

The subdivisions of the *Terebratulidæ* or lamp-shells, which include the most characteristic living forms of the Brachiopodous class, are based upon modifications of the brachial appendage. The foramen in the ventral valve is usually more or less formed by a small separate shelly piece called the *deltidium*.

The viscera and shell-muscles occupy a small space near the hinge; the rest of the shell-cavity is almost wholly occupied by the two long fringed arms, which diverge from the sides of the mouth and terminate in spiral coils (fig. 9, *f*).

Of the muscular system, the *adductor longus anticus* is shown at *o* (fig. 8); the *adductor longus posticus* at *p* (figs. 8 and 9); the *adductor brevis* at *q*. Other parts of the complex muscular system are described and figured in Owen's *Anatomy of Terebratula*,—*Introduction to the British Fossil Brachiopoda*, by Davidson, printed for the Palæontological Soc. 1853.

The stem of the brachia is hollow (fig. 9, *e*), and contains muscular fibres so disposed as to compress the fluid contained in the cavity. The nervous system consists of three principal parts—the "pallial," brachial," and "visceral;" the origins of these systems centre in the ganglionic basis of the cesophageal ring, which basis determines the dorsal and ventral aspects of the body as above defined. The details of the nervous system are described and figured in the *General Introduction to the British Fossil Brachiopoda*, above cited, p. 11, pl. 2; and in Owen's *Lectures on Invertebrata*, 8vo, 1855, p. 491.

The mouth of the *Terebratula* (fig. 9, *a*) is situated in the

Fig. 9.
Waldheimia flavescens (magnified).

middle line, and opens ventrad above the fringed transverse bar or common base of the brachia, and at the beginning of the passage formed by the spiral fold of the brachia; a short cesophagus ascends dorsad, and swells into the stomach, which curves backwards and downwards to *b*; the major part of the cavity is concealed by the hepatic follicles *d*, *d*;

¹ *Mémoires de l'Acad. Imp. de St Petersburg*, tom. i., p. 205, 1831.

² Gr. for "cloak-gilled."

³ Dim. of *terebratus*, perforated; in reference to the hole for the peduncle.

⁴ *Phil. Trans.*, 1851.

⁵ Gr. *αἰγερ*, a joint; *πυμ*, a valve.

⁶ Gr. for "arm-feet."

Brachio-
poda.

the intestine *e* is short, and terminates near the ventral valve behind the *adductor posticus*. The writer of the present article has detected fecal masses of infusorial shells in this intestine, and has pressed such out of the intestine in young specimens of *Terebratula caput-serpentis*, recently dredged: but the anus appears to become obliterated in some mature *Terebratulæ*.

The mantle lobes are remarkable for the size of the branched vessels of their inner layer, and for the tubular processes of the outer layer, which penetrate the pores of the shell. The trunks of the pallial vessels are connected with organs (fig. 9, *e*), discovered in the *Terebratula flavescens*, and first described as "a small transversely-plicated membranous process, continued from each side of the beginning of the intestine."¹ The homologous organs were soon after independently discovered in *Lingula anatina* by M. Vogt,² who described them as "peculiar sacs," lying one upon each heart, with its free border folded like a frill. "At the connecting line of the folds there is a fissure which leads to an extremely delicate canal, whose further continuations I could not follow; but it seemed to me that it opened externally between the two lobes of the mantle."³

The present writer, having subsequently convinced himself of the communication of these plicated organs with the visceral sinuses and ramified pallial vessels, described them as having the relation of auricles or hearts to that vascular system.⁴ Lovén⁵ concludes, from their external orifices, that they are kidneys; Mr Hancock⁶ that they are oviducts. The latter author conceives that the pallial vessels circulate, not blood, but sea-water, and compares them to the atrium of the Ascidians, and the water-chambers of the Cephalopods. He confirms the connection of this system of vessels with the plicated organs, the relations and varying conditions as to size of which are figured in the *Anatomical Introduction* above quoted, pl. 3. The ramification and subdivision of the pallial vessels near the margin of the mantle, the complex fringe of setigerous (*Terebratula*) or jointed (*Lingula*) bristles at their free margins, the modifications and developments of the inner layer of the mantle, described by Cuvier as "gills" in *Lingula*, and the perforating pallial tubuli discovered by Dr Carpenter,—all point to the respiratory function of the pallial lobes. The present writer has, however, observed ciliary actions on the fringes of the brachia in a living *Terebratula caput-serpentis*; and has remarked that "wherever the blood is exposed in its vessels and sinuses to the sea-water, a respiratory action must go on."⁷ A slender filament⁸ accompanies the larger pallial vessels throughout all their ramifications. The generative cells (testes or ovaria) are developed within the pallial vessels, and apparently from the more slender ramified body.⁹ In a *Lingula anatina*, preserved in spirits, the writer has observed the following stages of development in ova taken from the ramified pallial ovary, which was bathed in the fluid of the correspondingly ramified sinuses:—1st, An impregnated ovum, in which the germinal vesicle had disappeared and the germ-mass had been formed; it occupied the entire ovum, which had assumed an oblong form; a peripheral stratum of the derivative germ-cells was more compact and of a somewhat lighter colour than the central mass. 2d, A germ, showing the formation of a smooth membrane round the germ-mass. 3d, A germ

Brachio-
poda.

with a central cavity and the rudiment of a peduncle. 4th, An embryo with the peduncle more produced, but without a visible trace of the shell. These stages are described and figured in the *Anatomical Introduction to the Fossil Brachiopoda*, p. 22, pl. 1, fig. 7, *a* to *c*. They show that the young *Lingulæ* are provided with a peduncle before they quit the parent; and it is very improbable that they escape through the plicated organs which Mr Hancock regards as oviducts.

The first step in the investigation of a small and complex Mollusk, especially when, as a rarity, it is brought preserved in spirit to the anatomist, is to find, describe, and figure the structures that exist; the determination of their function, when found, is the work of ulterior research, and in regard more especially to the circulation, depends upon observations of the living animals. The present writer has derived much satisfaction in finding almost all the parts and organs which he had described and figured in successive contributions to the anatomy of the *Brachiopoda* confirmed by later investigators, with a difference of opinion as to the function of some parts, and a change of name of other parts. The anus of the *Terebratula*, *e.g.*, is described and figured by Mr Albany Hancock in the beautiful drawing of the dissection of the *Waldheimia flavescens* which he contributed to Dr Gray's *Catalogue of the Mollusca Brachiopoda of the British Museum*, 12mo, 1853, p. 14, fig. 2,¹⁰ "v vent," also in the figure published in Mr Woodward's *Manual of the Mollusca*, p. 210; and in Mr Davidson's *Classification of the Brachiopoda*, Palæontographical volume for 1853, p. 55, fig. 1. But in specimens subsequently dissected, Mr Hancock states he has not been able to detect the outlet at the end of the intestine. The same author, while he admits that the walls of the brachial canal (fig. 9, *e*) are supplied with delicate muscular fibres, which run diagonally round the tube, and which are crossed by "delicate longitudinal fibres," failed to detect anything like the "double spiral arrangements of fibres" described by Professor Owen. Whether science really gains by such changes of nomenclature as of "occlusors" for "adductors," and of "adjustors" for "protractors," may be questioned.

Genus TEREBRATULA (as restricted by Davidson).—Shell oval, elongated, or transverse, externally smooth or plaited; valves more or less unequally convex; margin even or waved; hinge-line curved; beak short, truncated by a foramen, partly margined by a deltidium in one or two pieces; appendicular (internal) loop short, attached to the dorsal valve; brachia projecting considerably in front of the loop; no internal septum in the ventral (socket) valve.

Sp. *Terebratula vitrea*, Glassy Lamp-shell.—Habitat Mediterranean, in 90 to 250 fathoms. More than 100 species of *Terebratula* with short loops have been found fossil. They range from the Devonian epoch to the present day. Of the fossil species the most remarkable is the *Terebratula diphya* of Colonna, from the Oolite of Italy. Both valves are perforated in the mid-line, in the same perpendicular, in advance of the hinge. Mr Woodward¹¹ states that the young had bi-lobed valves, which united in the adult so far as to leave the above apertures.

Genus TEREBRATULINA, D'Orb.—Shell generally longer than wide, more or less oval, finely striated; deltidium small; in some obsolete loop short, becoming annular in the

⁴ R. Owen, "Lettre à M. Milne Edwards sur l'appareil de la Circulation chez les Mollusques de la classe des Brachiopodes," *Ann. des Sc. Nat.*, 3ième Série, iii., 1845, *Zool.* pp. 315–320, plate 4.

⁵ *Annals of Natural History*, Aug. 1857, p. 145.

⁶ First described and figured by Owen as "arteries" in *Trans. Zool. Soc.* i., pl. 22 and 23. The impressions of these delicate filaments and vessels are sometimes preserved on fossil shells of *Terebratulites* that have ceased to exist since the Permian period,—*e.g.*, in *Carnarophoria multiplicata*. (King, *Monograph of English Permian Fossils*.) By virtue of the minute radiated spicula of carbonate of lime with which the mantle, brachia, and brachial cirri are, as it were, frosted over, the preservation of these delicate soft parts, or of instructive indications of them, in fossil Brachiopoda, seems due.

Brachio-
poda.

adult by the union of the oral processes, forming a shelly band behind the mouth.

Sp. *Terebratulina caput-serpentis* (Snake-headed Lamp-shell).—Hab. from Norway to the Mediterranean, at from 10 to 150 fathoms. About twenty fossil species are known; ranging from the Oolitic to the actual epochs.

Genus *WALDHEIMIA*, King.—Shell smooth or plaited, with the dorsal valve impressed, in some species depressed or concave; perforation of beak completed by a deltidium of one or two pieces; loop long, usually exceeding two-thirds of the length of the valve, and reflected; septum of dorsal valve elongated.

Sp. *Waldheimia flavesceus* (*Terebratula australis*, Quoy and Gaim.)—Hab. Australia, from just below low-water mark to 20 fathoms. This is the species of which the anatomy is illustrated in the *Anatomical Introduction to the British Fossil Brachiopoda* above cited, and in fig. 9 of the present article.

Terebratulidæ with long loops have been found from the Lias to the present period.

Genus *TEREBRATULA*, D'Orb.—Shell smooth, or with radiating folds; dorsal valve longitudinally impressed in most; beak-hole partly margined by a deltidium of two pieces, in some disunited above the umbo; beak with a flattened area on each side of the deltidium; loop elongated and attached to the septum as well as to the hinge.

Sp. *Terebratella dorsata*, Lam.—Hab. Straits of Magellan. The soft parts and apophysary system of the genus were described from this living species in the *Transactions of the Zoolog. Society*, vol. i., p. 141, pl. xxii., 1835. The species of this genus, now ranked under sub-genera, range from the Cretaceous period to the present day.

FAMILY II.—THECIDIIDÆ.

The characters of the family are also those of the single genus composing it.

Genus *THECIDIUM*,¹ De France.—Shell thick, punctate, attached by the substance of the ventral shell at or near the beak; interiorly a deep or thick granulated margin generally encircles the valves, and in the ventral one, after reaching the front, extends inwards in the shape of a rounded mesial ridge; oral processes united, forming a bridge over the visceral cavity; loop often unsymmetrical, lobed, and united more or less intimately with the sides of the grooves.

Sp. *Thecidium mediterraneum*.—Hab. Mediterranean; attached to corals. The animal has elongated brachia folded on themselves, with their curve long and not close-set.

"This genus, so far as we know, first appeared in the salt-marls of St Cassian. In the Lias the species are both numerous and large; from that epoch the genus continued uninterrupted to the present period, and the family is still represented by a single species." (Davidson's *Monograph*, above cited.)

FAMILY III.—SPIRIFERIDÆ, Sowerby.

All the species are extinct; they were chiefly distinguished by much-developed brachia, supported on spirally-disposed shelly processes, which were sometimes spinulose.

Davidson admits five genera and two sub-sections of this family. The species range from the lower Silurian epoch through all the Palæozoic formations, and apparently died out in the Lias.

FAMILY IV.—RHYNCHONELLIDÆ.

Shell impunctate, oblong, or trigonal beaked; hinge-line curved; no area; valves articulated, convex, often sharply plaited; foramen beneath the beak, usually completed by a deltidium, sometimes concealed; hinge-teeth supported by dental plates; hinge-plate deeply divided, supporting

oral lamellæ, rarely provided with spiral processes; muscular impressions grouped as in *Terebratula*; vascular impressions consisting of two principal trunks in each valve, narrow, dichotomizing, angular, the principal posterior branches inclosing spaces which leave punctate impressions in casts of the shell.

Genus *RHYNCHONELLA*,² Fischer (*Notice des Fossiles du Gouv. de Moscow*, 1809).—Animal with elongated spiral arms directed inwards towards the concavity of the dorsal valve; visceral mass scarcely extending beyond the umbones, separated from the general cavity of the shell by an aponeurosis, in the centre of which is the mouth; labia united at the sides of the mouth and produced into the spiral brachia; alimentary canal terminating behind the insertion of the adductor in the ventral valve; mantle not adhering, its margin fringed with a few short setæ.

Sp. *Rhynchonella psittacea*.—Hab. northern seas. The organization of this recent species is illustrated in the *Transactions of the Zool. Society*, vol. i., 1835, p. 145.

Rhynchonella nigricans.—Hab. New Zealand. The above are the only two existing species at present known. Upwards of 250 species of this family have been found fossil. It manifests one of the most ancient types of animal organization, ranging from the Cambrian to the present period. The chief modifications of the family type were exemplified by the extinct genera *Pentamerus*, Sowerby; *Camarophosia*, King; *Atrypa*, Dalman.

FAMILY V.—ORTHIDÆ.³

Shell transversely oblong, depressed, rarely foraminated; hinge-line wide and straight; beaks inconspicuous; valves plano-convex, or concavo-convex, each with a hinge-area notched in the centre; ventral valve with prominent teeth; muscular impressions occupying a saucer-shaped cavity with a raised margin; adductor central; cardinal and pedicle impressions conjoined, lateral, fan-like; dorsal valve with a tooth-like cardinal process between two curved brachial processes; adductor impression quadruple; vascular impressions consisting of six principal trunks in the dorsal valve, two in the ventral, the external branches turned outwards and backwards, inclosing wide spaces called ovarian. Indications have been observed in several genera of horizontally-coiled spiral arms, but they had no calcified supports; the space between the valves is often very small. The shell-structure is minutely tubular or punctate, except in a few instances, where the original texture is probably obliterated.

All the species are extinct; some appear to have lived free, others to have been fixed by means of a pedicle. They range from the Cambrian to the end of the Liassic period: the type genus *Orthis* has not been found above the Carboniferous formations.

FAMILY VI.—PRODUCTIDÆ.

Shell concavo-convex, with a straight hinge-line; valves in some species (*Stropholosa*, King) regularly articulated, in others without hinge-teeth; closely appressed, striated,—the striæ developing close-set tubular spines; ventral valve convex; dorsal valve concave; internal surface dotted with conspicuous funnel-shaped punctures; dorsal valve with a prominent cardinal process; brachial processes sub-central, without calcified supports; vascular markings lateral, broad, and simple; adductor impressions dendritic, separated by a narrow central ridge; ventral valve with a slightly notched hinge-line; adductor scar central, near the umbo; cardinal impressions lateral, striated.

All the species are extinct: they range through the Devonian, Carboniferous, and Permian periods.

Brachio-
poda.

¹ Gr. for "small pouch."

² Gr., sign. "small beak."

³ Gr. for "straight."

Brachio-
poda.ORDER II.—LYOPOMATA, Owen.¹

Shell-valves inarticulated, and, save in the annectant family *Craniada*, subcalcareous; viscera occupying one-half, brachia the other half, of the shell cavity.

FAMILY I.—CRANIADÆ.

Shell orbicular, hingeless; external surface smooth, or spinous, or with radiating costæ or foliaceous expansions; dorsal valve limpet-like; interior of each valve with a broad granulated border, well exhibiting the tubular or punctate shell-structure; disk with four large muscular impressions, and digitated vascular impressions.

Genus CRANIA, Retzius, 1781.—Animal usually attached by the substance of the ventral valve, with free spiral arms directed towards the concavity of the dorsal valve, and supported by a nose-like prominence in the middle of the lower valve; mantle-lobes extending to the edges of the valves, and closely adhering, with the margins plain and thin.

Sp. *Crania anomala*, Müller.—The thick, cirriferous, spiral, labial arms are confined to the anterior half of the shell-cavity, and are devoid of calcareous supports; the pallial sinuses are digitate.

"The valves of *Crania* appear to have been opened by the action of sliding muscles, as described by Professor Owen in *Diseina*; those which advance the dorsal valve (*protractor* muscles) are aided by a single small muscle in the median line, answering to the *cardinal* muscle of *Terebratula*. The pair of muscles which bring the free valve back to its place (*retractors*) are attached outside the anterior adductors of the free valve, and to a point between the posterior adductors in the fixed valve, like their equivalents in *Discina*, according to Owen."²

The species of *Crania*, most of which are now extinct, range from the Cambrian to the present period.

FAMILY II.—DISCINIDÆ.

Shell-valves unarticulated, minutely punctate; animal attached by a very short and thick mass of musculo-tendinous fibres, passing through the ventral valve by a slit in the hinder portion, or by a circular foramen.

Genus DISCINA,³ Lam. (*Orbicula*, Broderip and Sowerby).

Sp. *Diseina* (*Orbicula*) *lamellosa*, Brod. The following are notes of dissection of two specimens of this species, which were given to the writer by Mr H. Cuming, who collected them on the Peruvian coast:—The shell is of an irregular, rounded, flattened form, of a reddish-brown colour; the edges of the layers of increase are horny, and the margin of the shell is of a soft texture and thickened. The layers of increase are large in proportion to the size of the shell, and very irregular; the dorsal valve resembles that of a low limpet, having the apex behind the centre; the ventral valve is flat. The orifice in the ventral valve is a slit at the bottom of a depression; it is three lines long and half a line wide. Through this slit the organ of adhesion passes, and immediately expands into a round sucker, which fills up the whole of the depression, concealing the margins of the slit. Beyond the margins of the valves long shining setæ project from two to four lines, which are inserted all round the free or disunited margins of both lobes of the mantle; but the outer shell-forming layer of the mantle extends a little beyond the setigerous border. The setæ are much longer in proportion than in *Terebratula*, and rather longer than in *Lingula*; they are beset with minute *setulæ*. The muscles and viscera are situated in a rounded mass in the posterior half of the shell. At the fore-part are two oblong ends of muscles with their anterior sides converging; in the triangular space between them is the green-coloured liver;

Brachio-
poda.

behind these the mass of the gray ovary; and at the posterior part of the circle are two smaller "post-adductor" muscles.

On removing the lower valve, which must be cut through to the fissure on each side in order not to disturb the viscera, the same structure of mantle is perceived, there being a single vascular trunk or sinus on either side; but the viscera are quite concealed by the dilated disc for adhesion. On removing the mass of the follicular liver and ovary, the alimentary canal is observable extending down the middle to the posterior part of the shell, and then bending to the right, viewed from behind, it enters the right egg-receptacle, and terminates by opening externally between the mantle-lobes and just behind the right extremity of the arm. Four shining tendons are also observable: two superior diverging. The two superior pairs arise by a common origin from between the insertion of the anterior large muscles, and are inserted outside the posterior pair of muscles; and two inferior converging, to be inserted at the inner side of the same. These are attached by their opposite extremities to the sides of the membranous circle containing the ova, and protecting the viscera. The two posterior large muscles are inserted into the lower valve close to the slit.

On turning down the ventral lobe of the mantle, the vessels are also seen converging from the respiratory margin to two trunks, which terminate in two oblong plicated cavities on either side. These are the hearts of the pallial sinuses ("kidneys" of Lovén, "oviducts" of Hancock); they are situated between the two strong membranes which circumscribe the visceral mass, and divide it into two cavities. These cavities are large, and were filled with a coagulated light-gray substance and a brownish matter; the latter, under the microscope, presented a granular appearance, like ova, but the lighter substance had no form or structure; it might be coagulated blood. The arms are joined at their bases below or across the ventral side of the mouth, on which aspect they form a transverse, semilunar, fleshy stem, fringed and convex anteriorly; at the extremities of this ridge they are bent upon themselves, and turn upwards and forwards their extremities, making one turn and a half in front of the mouth. These reflected parts of the arms are closely connected to the first-described portion, and cannot be freely everted and protruded, as in *Lingula*. The lateral parts, where the bend is, may be pushed out like elbows, and so the shell be opened; or it may be opened by their contracting from the bend towards the mouth, and so becoming thicker and opening the shell. The brachial fringe consists of round equal filaments, with an entire surface; but when viewed through the lens, dark lines seem to traverse them longitudinally.

The *Discinidæ*, of the genus *Trematis*, Sharpe (*Orbicella*, D'Orb.), as well as those of *Siphonotreta*, De Vernueuil, belong to the Silurian periods. The species of *Orbiculoides*, D'Orb., range from the Silurian to the Neocomian periods, and were most numerous during the Carboniferous period. The true *Diseinæ*, as restricted by D'Orbigny, first appeared at the Tertiary epoch, and are still represented by the species which the writer has had the opportunity to anatomize.

FAMILY III.—LINGULIDÆ.

Shell oblong or orbicular, sub-equivalve, attached by a long pedicle passing out between the beaks of the valves; texture horny, minutely tubular; arms fleshy, unsupported by calcified processes.

Genus LINGULA,⁴ Bruguière, 1789.—Shell oblong, compressed, slightly gaping at each end, truncated in front, rather pointed at the umbones; dorsal valve rather shorter, with a thickened hinge-margin and a raised central ridge inside.

¹ *λίσσω*, to loosen; *πυμα*, valve.

² Gr., signifying "small plate."

³ Davidson, *Monograph on British Brachiopoda*, p. 123.

⁴ Lat., "a little tongue."

Brachio-
poda.

Animal with the mantle-lobes firmly adhering to the shell, and united to the epidermis, entire circumference of their margins distinct, and fringed; pallial sinuses giving off numerous narrow loops from their inner surfaces; visceral cavity occupying the posterior half of the shell, and surrounded by a strong muscular sheath; pedicle elongated, thick; adductor muscles three, the posterior pair combined; two pairs of retractors, the posterior pair unsymmetrical, one of them dividing; protractor sliding muscles, two pairs; stomach long and straight, sustained by inflections of the visceral sheath; intestine convoluted dorsally, terminating between the mantle-lobes on the right side; oral arms disposed in about six close whirls, their cavities opening into the prolongation of the visceral sheath in front of the adductors.

Sp. *Lingula anatina*, Lam.—From dissections of this species, the Brachiopodous type of structure was first made known in the memoir by Cuvier in the *Annales du Muséum*, vol. i., 1802. Cuvier here shows, in *Lingula*, a condition of the respiratory organ which might be paralleled with one of the transitory states of that organ in the Lamellibranchs,—that, viz., in which the rudimental gills appear as processes from the inner surface of the pallial lobes, and in which the distinction, whether morphological or physiological, of the gills and mantle is not fully established. The modifications of the breathing organ in both *Terebratula* and *Discina* exhibited a more interesting condition, comparable to a still earlier stage of the respiratory system in the embryo Lamellibranch,—that, viz., in which the vessels of the pallial lobes have not begun to bud out in parallel rows of vascular loops,—the first stage in the formation of gills, and the one at which it is arrested in the *Lingula*. Additional particulars of the organization of *Lingula* will be found in the *Transactions of the Zoological Society*, vol. i.; in the *Anatomie der Lingula anatina*, by Vogt; in the *Neuer Denkschrift der Schweizerischen Gesellschaft*, Bd. vii.; and in the *Introduction to the Monograph on British Fossil Brachiopoda*, pl. i., figs. 5, 6, and 7; pl. ii., fig. 3.

The high antiquity of the *Lingula*, and the maintenance of the genus under very slightly modified specific representatives to the present day, render a knowledge of so enduring a plan of organization highly interesting. Fossil *Lingula* (*L. Davisii*, M'Coy, *e.g.*) occur in the Cambrian or lowest fossiliferous beds of North Wales; and *Lingula* continued to exist in the seas that are now British as late as the period of the Coralline Crag. The genus is represented at the present day by living species, which as yet have only been found in warmer latitudes; *e.g.*, in the seas washing the coasts of the Indian Archipelago, the Moluccas, Australia, the Fiji and Sandwich Islands.

The *Lingula anatina*, living near the surface, and sometimes where it would be left exposed by the retreating tide were it not buried in the sand, must meet with more variety and abundance of nutriment than can be found in the deeper waters, where *Terebratula*, *Crania*, and *Discina* usually reside. Hence its powers of prehension are greater; and Cuvier suspects that it may even enjoy a species of locomotion from the superior length and muscularity of its pedicle. The organization of its mouth and stomach indicates the molecular character of its food; but its convoluted intestine shows a capacity of extracting a quantity of nutriment proportioned to its superior activity, and to the greater extent of its soft parts. The more extended pallio-vascular surface is in harmony with the above conditions of structure and habits.

With regard to *Discina*, and more especially the deep-sea species of *Terebratula*, both the respiration and nutrition

of such animals—which exist beneath a pressure of from sixty to ninety fathoms of sea-water—are subjects suggestive of interesting reflections, and lead one to contemplate with less surprise the great strength and complexity of some of the minutest parts of the frame of these diminutive creatures. In the unbroken stillness pervading those abysses their existence must depend upon their power of exciting a current around them in order to dissipate the water already laden with their effete particles, and to bring within the reach of their prehensile organs the animalcules adapted to their sustenance.

The Brachiopods appear to have been most abundant, and certainly manifested their most varied forms, in past epochs of the globe. They are now, though comparatively few in number and restricted in generic modifications, widely diffused over the earth's surface; and some species exist at greater depths than other bivalve Mollusks. They are thus amongst the most ancient of existing types of animal structure, and their range in space is as extensive as has been their range in time.

With regard to the affinities of the *Brachiopoda*, Siebold¹ compares their spiral-fringed brachia to the tentacles of *Alcyonella*; and this idea of their affinity to the *Bryozoa* has been reproduced and supported by Mr Hancock² and Professor Ailman, who deem the affinities of the *Bryozoa* to pass off in two directions,—in one through the *Tunicata*, and in the other through the *Brachiopoda*; but they believe the *Brachiopoda* to be much more nearly allied to the *Lamellibranchiata* than they are to the *Bryozoa*.³ Cuvier indicated his sense of the distinct and well-marked type of the structure of the *Brachiopoda* by placing the class below that of the *Tunicata*,—a position which it retains in the edition of the *Règne Animal* of 1830.

The knowledge of the structure of the mature forms of *Terebratula*, *Waldheimia*, *Rhynchonella*, *Crania*, *Discina*, or *Orbicula*, and *Lingula*, led the writer in 1835 to regard the *Brachiopoda* as a group equivalent to the *Tunicata* on the one hand, and to the *Lamellibranchiata* on the other; and in the linear series, necessitated by progressive description, the proper place of the *Brachiopoda* was deemed to be, as in the present article, between the *Tunicata* and the *Lamellibranchiata*. Should the embryology of the *Brachiopoda* show that they propagate by gemmation as well as by impregnated ova, and that the embryo quits the ovum under the guise of a ciliated gemmule, such facts would weigh strongly for the closer affinity of the *Brachiopoda* to the ciliobranchiate Polypes. Should the *Brachiopoda* be found to propagate exclusively by impregnated ova, and—as the scanty observations on *Lingula* show that the embryo undergoes a development which brings with it a recognisable approach to the mature form before it quits the parent—should the little embryonal Brachiopodous Bivalves be found also to be hatched in the sinuses of the respiratory layer of the pallial lobes,—all these developmental characters will tend to confirm the position which is here assigned to this well-defined class of Acephalous Mollusks.

CLASS III.—LAMELLIBRANCHIATA.⁴

(*Acephales Testaces*, Cuvier; *Bivalvia*, Fleming).⁵

Approximations to the characters of the Lamellibranchiate Bivalves are made in the foregoing class by *Rhynchonella*, in respect to the structure of the shell, by the absence of the minute canals and co-adapted pallial tubes which traverse the shell in other Brachiopods; in respect to the mantle, by its being consequently less adherent to the valves; and in respect to the oral brachia, by the rudi-

Lamelli-
branchiata.

mentary condition of their calcareous supports, and by their consequent greater freedom and mobility, in which they resemble the long labial palps of *Anomia*. A like approximation is made by *Lingula* in the complexity of the inner respiratory layer of the free lobes of the mantle, and in the proportion of the shell-cavity occupied by the visceral mass. Reciprocally, the genera *Anomia* and *Ostrea*, among the Lamellibranchs, resemble the *Brachiopoda* in the attachment of the shell to foreign bodies by either its substance or by altered muscular fibres, and in one valve being downwards, the other upwards; so that they are distinguished into "lower" and "upper" valves, in the position in which the living animals are commonly found. The lobes of the mantle, moreover, are as little united as in most *Brachiopods*; and the generative glands are developed in a ramified form upon them in *Anomia*; in which genus, finally, the muscles of the shell and pedicle or plug present a complexity almost equal to those in *Discina*.

The homology of the "pallial lobes" of *Brachiopoda* with the same-named parts in *Lamellibranchiata*, and of the mouth and its labial productions in *Lingula* with those in *Anomia*, may be as true as it seems obvious; but in *Acephala*, developed on plans so different in the general disposition of the soft parts in the shell, the grounds for determining special homologies are by no means so satisfactory and convincing as in the different members of the animals organized on the same vertebrate type. The principle of a final purpose more obviously governs the number and position of the shell-muscles in *Discina* and *Anomia*, than any uniformity of plan to which such resemblance might be referred. But the dogmatic assertion of the abstract nature of the correspondences above cited, as being, *e.g.*, of "analogy," not of "affinity," will not close the eyes of the impartial observer of nature to their presence and probable signification.

We have seen that the relation of the soft parts to the bivalve shell of the *Brachiopoda* is such that one valve is "ventral," the other "dorsal" in position. In the *Lamellibranchiata* one valve is applied to the right side, the other to the left side of the animal. The ciliated labial tentacles, as compared with those in the *Brachiopoda*, are short, and are more glandular than muscular; and there is usually a pair on each side of the mouth (fig. 11, *h*). Most of the *Lamellibranchiata* are free and locomotive. The instrument by which they move from place to place is a single symmetrical muscular organ (fig. 10, *e*) developed from the

valve to valve is two. They are called "adductors," and are antagonized by an elastic substance, so inserted at the hinge uniting the two valves as that it is squeezed when the shell is closed, and opens the shell when the adductor muscles relax. The visceral mass occupies about half the cavity of the shell next the hinge (fig. 11); the rest of the interspace of the pallial lobes is chiefly occupied by the "foot," when this is developed, and by the "branchiæ." The breathing organs (fig. 11, *p, p*) are mostly lamellose, or shaped like long subrescentic leaves or plates, two on each side, dependent from the inner surface of the mantle-lobes (fig. 11, *a*). This characteristic of the breathing organs gives its name to the present class of Acephalous Mollusks. The heart consists of a ventricle with usually two auricles; and as a rule, the ventricle is traversed by the end of the intestine (fig. 17, *q*). An excretory organ, developed from the veins near the heart, communicates externally by the pericardial or aquiferous outlet. With the exceptions above mentioned the Lamellibranchiate Bivalves live with the back uppermost, resting on the ventral edge of their shell, as in the position of the sand-shell *Psammobia* (fig. 10).

True Bivalves, as a general rule, are dioecious and ovoviviparous.

The well-known oysters, cockles, mussels, razor-shells, and ship-borers, exemplify the present class of *Mollusca*, of which all the members are aquatic, and most are marine.

The bivalve shell of the Lamellibranchs (fig. 12) offers, as might be expected, many modifications corresponding in general with those of the mantle, but otherwise related in a few species to boring habits and a peculiar locality; other calcareous parts in a tubular or other form being then usually superadded. The shell consists essentially of an organized extra-vascular combination of albuminous membrane and calcareous earth, chiefly carbonate of lime, arranged in successive layers. The innermost is the largest and latest formed, and each layer presents a

Fig. 12.
Cytherea.

cellular, lamellar, or prismatic texture, which presents characteristic variations in different families.¹ Each valve of the normal shell is a cone, showing every grade of depth from the flat plate of the *Placuna* to the produced and spiral cavity of *Isocardia* and *Diceras*; it is commonly shallow, with the apex or *umbo* turned more or less to one side and directed forwards. If you place a bivalve

shell in the position of the *Cytherea* (fig. 13), the direction of the *umbo* determines A as the anterior border, and P as the posterior one; the upper or dorsal, and the lower or ventral borders, are as marked in the cut. The length of the shell is taken from A to P; its height or breadth at right angles from the dorsal to the ventral border; its thickness is measured across the closed valves, at the most prominent part from the right to the left side of the animal, as shown in fig. 12. Transfer yourself in imagination within the shell (fig. 13), with your head towards A and your back towards the dorsal border, and you will recognise the valve figured as the *right* valve. Anterior to the *umbo* there is usually an oval depression, forming a concavity in the outline

Fig. 10.
Psammobia florida.

ventral surface of the visceral mass. The body, and usually also the shell, is longer in proportion to its depth than in *Bra-*

Lamelli-
branchiata.

of the valve; it is called the *lunule*. The hinge ligament is sometimes between the *umbones*, never anterior to them. If the shell be divided by a line dropping from the apex of the *umbo* into an "anterior" and "posterior" part, it is never

Fig. 13.
Cytherea chione.

equally divided; in other words, it is unequilateral. *Pectunculus* is least so; in *Glycymeris* and *Solemya* the anterior moiety is longer than the posterior one; in almost all other Bivalves it is shorter, as in *Cytherea* (fig. 13); commonly it is much shorter. Most Lamellibranchs are *equivalve*; that is, the right and left valves are of the same size and shape as in *Cytherea* (fig. 12). The exceptions occur in the stationary and often fixed species, which lie on one side when the lower valve is deeper and more capacious than the upper one. This lower valve in the oysters (*Ostrea*), in *Pandora*, and *Lyonsia*, is the left valve; the smaller and flatter upper valve is the right one. In *Chamostrea* and *Corbula* the left is the smallest valve. The *Placuna*, *Pectines*, *Spondyli*, and *Aviculidæ* rest on the right valve; the *Anomæ* are attached by degenerated muscular fibres passing through a hole or notch in that valve to a more or less calcified lamellar plug. All these shells are called *inequivalve*.

The bivalve is called *close* when the valves fit accurately; it is *gaping* if part of the borders do not come into contact when the shell is shut. In *Gastrochæna* this permanent opening is anterior, and serves for the passage of the foot. In *Mya* it is posterior, and serves for the passage of the byssus; in *Solen* and *Glycymeris* the shell gapes at both ends.

The outer surface of the shell is usually coated by an uncalcified layer of albumen called the periostracum or epiderm, continuous with the mantle. This surface is variously ornamented in many species, sometimes with ridges or "ribs," which may be either *concentric* and conformable with the layers of growth, or *radiating* from the umbones to the free margins of the valves; and the ribs may be bent, direct, oblique, or wavy. In *Tellina fabula* the sculpturing is confined to the right valve. In many species of *Pholas*, *Teredo*, and *Cardium* the surface is divided into two areas by a dorso-ventral furrow or by a change in the direction of the ribs. The thorny oysters (*Spondylus*) are so called on account of the spines which project from the rib-lines; they are longest and in greatest number upon the non-adhering valve. In some conditions of the shell the spines expand into foliaceous forms.

The part where the two valves are joined together is called the hinge. The *cardinal* or hinge-line is short in *Vulsella*, long and straight in *Avicula* and *Arca*; of moderate length, and curved in most genera. The locomotive Bivalves have generally the strongest hinges; however, a very well-developed example of the hinge mechanism may be studied in the *Spondylus*. Certain projections or teeth of one valve interlock into cavities in the opposite valve.

The central teeth, usually beneath the umbo, are called *cardinal teeth*; those on each side are *lateral teeth*. The *Alasmodon* and *Kellia* have only lateral teeth; in many Bivalves only cardinal teeth are present. The teeth are apt to become thickened and even obliterated by age, through irregular growth, or by the encroachment of the hinge-line. Some of the fixed and boring Bivalves are edentulous.

The soft mechanism of the hinge consists of the *ligament* and *spring* (fig. 16, T, b). The ligament is a tough, thickened portion of albuminous matter like that of the periostracum, and is usually attached to ridges on the outer (dorsal) part of the hinge-margin, behind the umbones; it is consequently stretched by the closing of the valves. The *spring*, sometimes called "internal ligament," and (though improperly) the "cartilage," is lodged in the furrows between the ligamental plates, or in pits along the hinge-line. It is composed of elastic fibres placed perpendicularly to the surfaces of attachment, so as to be compressed by the shutting of the shell, which the elastic fibres consequently tend to open as soon as the action of the adductors ceases. The two parts are very distinct in the genus of Bivalves, thence called *Amphidesma* (double ligament), but they co-exist in most genera, with alternate proportions; the ligament being small in *Mastra*, which has a large "spring," and large in *Anodon*, which has a small "spring." The *Pholades* have the spring, but have not the ligament. This is replaced by the homologue of the anterior adductor, which is so situated as to act as an opener of the shell, and is called the "umbonal muscle." The functions of the shell in this boring Bivalve are too active and too frequently in exercise to be performed by the passive antagonist of the muscular closing powers which suffices for ordinary Bivalves.

The formation and repair of the shell are due to the development, change of form, and calcification of cells from the mantle; the nucleated cells of its outer surface being the matrix of the nacreous layer, its thick and periodically glandular margin that of the opaque outer portion.

The microscopic structure of bivalve and univalve shells has been well illustrated by Professors Carpenter¹ and Quekett.²

The primitive nucleated condition of the cell is sometimes retained after calcification. The dissolved lime-salts, after endosmotic penetration of the organic walls of the modelling cell, obey so far the general crystallizing force as to polarize light. The forms of the constituent lime particles of the shell, so moulded by combined vital and polarizing forces, are manifold in the various genera of Bivalves. The shell of the *Pinna*, save a thin internal layer, is composed of vertical, slender, usually hexagonal prisms. A thin outer layer of the shell of the oyster also presents the prismatic cellular tissue; but in a great proportion of this shell nearly all trace of development from cells is lost. The gelatinous basis is lamelliform, and this variety is called the subnacreous shell-substance.

Fine tubes, analogous to those of dentine, permeate the thickness of this substance in many shells,—radiating vertically between the ribs in *Arca*, vertical and scattered in the inner layer, and reticulate in the outer foliaceous spines, of the shell of *Chama*, which has an intermediate layer of ill-defined vertical prisms. The prismatic structure is rarely found, and then only in small proportion, in the Bivalves which have the mantle lobes in any degree united. The distinction between the internal or nacreous layers and the external or fibrous layer, has long been recognised, and has been forced, as it were, upon the notice of the palæontologist by the circumstance of the two being often separated from each other in fossil shells, and sometimes from one having perished whilst the other remained. As the

Lamelli-
branchiata.

¹ Reports of the British Association, 1844 and 1847.

² Lectures on Histology, 8vo, 1853-4.

Lamelli-branchiata. nacreous layer alone forms the characteristic hinge uniting the two valves of the shell, and alone receives the impressions of the soft parts, the true characters of fossil shells, as those of the *Aviculidæ* and *Radiolites*, which, in consequence of their position in porous chalky beds, have lost all the nacreous layer, cease to be determinable, save when a natural mould of the interior has been formed before the pearly lining of the shell was dissolved. When the inner layer is preserved, its impressions reveal the organization of the ancient fabricator of the shell as clearly as do the forms and processes of fossil bones that of the extinct vertebrate animal. The layers of the thick subnacreous inner substance of the shell of the *Spondylus* have frequently wide interspaces, called, from their contents, "water chambers." This "camerated" structure is well shown in the right or lower valve of *S. varius*, fig. 19.¹

Fig. 14.
Cytherea chione.

In fig. 14, showing the internal surface of a *Cytherea*, the chief impressions are named. When two adductors are present, as in the Bivalves thence called "dimyary," they leave the anterior and posterior muscular impressions; when one adductor only exists, it answers to the posterior muscle, but is more central in position. The oyster is a familiar example of such "monomyary" Bivalve. When the pallial line or impression extends in an unbroken curve from the anterior to the posterior muscular impressions, it may be inferred that the inhabitant of the shell had either no siphon, or a very small or a non-retractile siphon; when the line is bent towards the centre before it reaches the posterior adductor, as in fig. 14, the presence of a retractile siphon is indicated, this notch being occupied by the retractile muscle of that part. When a foot is present, its retractor-muscles usually leave recognisable marks on the interior of each valve. The siphon in some of the elongated *Inchusa* cannot be retracted into the shell; they are consequently exposed, as in *Pholadomya* and *Pholas*; such species derive extrinsic shelter by burrowing in the sand or stone. The *Pholades* have supplemental calcareous pieces in the hinge of the shell: two small plates protect the umbonal muscles, and a long narrow plate fills up the dorsal interspace of the valves. The *Clavagella* (fig. 15) and *Aspergillum* line their burrows with a calcareous layer *d*, which forms in the latter (fig. 23) a distinct tube, closed at the larger extremity by a perforated calcareous plate. One of the valves of the normal shell adheres to the tube in the *Clavagella* (fig. 15, *f, g, h*), and both are cemented to its inner surface in the *Aspergillum* (fig. 23). In the *Teredo navalis* (fig. 25) the valves are reduced to mere appendages of the foot at one extremity of the animal, and are almost restricted in their function to the action of boring. As the ship-worm advances in the wood, it lines its burrow with a thin layer of calcareous matter. The length of the

body is chiefly due to the prolongation of each respiratory Lamelli-branchiata. tube, the siphon of which is provided with a small elongated calcareous triangular paddle-shaped plate. In the *Teredo gigantea* the calcareous tube, which sometimes surpasses

Fig. 15.
Clavagella lata.

6 feet in length, has parietes of from 4 to 6 lines in thickness, the texture of which is crystalized or spathose. Two tubes are developed within its siphonal end. In *Teredo norvegica* the calcareous tube is divided longitudinally, and also transversely, into compartments by irregularly-placed incomplete concave septa.

The valuable pearls of commerce are a more compact and finer kind of nacre, often developed in the substance of the mantle or around a particle of sand or other foreign body which has gained admission to the pallial cavity. The *Meleagrina* or *Avicula margaritifera* of the Persian and Indian seas is most famous for these productions; those developed in the gills or inner layer of the mantle are small and numerous; those of the outer layer are the largest but least regular, and are attached to the shell. The "external" pearls consist of a concentric layer of minute vertical prisms; the "internal" pearls of concentric layers of wavy calcified membrane.

The iridescent nacreous lining of the pearl oysters (*Avicula*), and many other shells, consists of the same wavy lamelliform tissue; the pearly lustre is due to the diffraction of the rays of light by the out-cropping edges of the laminae, and in some cases to the minute plication of a single lamina. (Brewster.)

If the shell of a living pearl oyster be perforated, and a minute particle of sand introduced, it becomes a nucleus round which a pearl is developed. Linnæus was knighted on making known to his sovereign this practical application of his science; but the artificial production of pearls had long been known to the Chinese, who obtain them of definite forms by introducing substances of the required shape into the shell.

The *Unio margaritifera*, or pearl mussel of British lakes and rivers, is fished up for the ornamental excretions to which it is subject. It is probable that the pearls from this source, collected by the ancient Britons, may have given rise to the statement of Tacitus, in his *Life of Agricola*, of "pearls not very orient, but pale and wan," being among the indigenous products of the conquered island.²

Lamelli-
branchiata.

The mantle (fig. 16, *ab*) is that portion of the skin of the Lamellibranch which, after investing the viscera, gills, and foot, is reflected, ventrad, in the form of plates and "lobes" to line the shell which it has formed, and be produced, when needful, into breathing-tubes. It consists of a middle layer of fibro-cellular tissue, in which contractile fibres are

entire Mollusk, as, *e.g.*, in *Cardium echinatum* (fig. 17, D). Lamelli-branchiata. The curious relation of the rectum (*P*) to the heart *Q* is shown in this figure. The position of the rectum in the *Pecten* may be seen at D (fig. 16). The circulation may be traced, beginning with the abundance of veins which

Fig. 16.
Pecten opercularis.

variously developed, of an internal layer of "ciliated epithelium," and of an external layer of epithelial cells, with nuclei, sometimes called "glandular epithelium."

The lobes of the mantle may be widely separated (*Ostrea*, *Pecten* (fig. 16, B, *b*); or partially united between the branchial and anal orifices (*Mytilus*); or united behind, leaving a single siphonal orifice; or united between the siphonal orifices and in front of the branchial opening; or the union of the mantle-lobes may be so extended as to leave a pedal or byssal opening, a branchial, and an anal opening,—all of small size (*Dreissena*); or finally, the mantle may become like a sheath, with terminal pedal and siphonal apertures (*Solen*); and the former may be reduced to a small foramen, and surrounded by a thick cushion of boring muscles, as in *Clavagella* (fig. 20).

The mantle is complicated in some Bivalves by glandular sacs (fig. 16, *a*), which sometimes contain a gaseous fluid subserving the Pectens,—*e.g.*, to float with their light shell, and change their situation at the ebb and flow of the tide. The Pectens, also, well exhibit the valvular reflected sub-marginal fold (fig. 16, *h*) of the mantle, the tentacula developed from that fold and from the free margin of the mantle (fig. 16, *b*), together with the eye-specks or ocelli *c*, near that margin.

The jawless and toothless mouth (figs. 16 and 17, C) is surrounded by a plicate (fig. 17) or tentaculate (fig. 16, F) labial border, produced into the labial palps (fig. 17, E), of very varying length in different Bivalves. The stomach (fig. 17, U) receives the hepatic ducts; and, save in most *Monomyaria*, develops a sac (fig. 17, V) containing the part called the "crystalline style," the gastric extremity of which (V) supports a thin cartilage, called the "tricuspid body" (fig. 17, *v*). The chief part of the style and of its sac is directed towards the pore by which water is admitted into the foot; and it has been conjectured to give some resiliency to that organ, with which it usually co-exists. In *Anomia*, however, it supports a free portion of the mantle. Poli supposed the tricuspid body to regulate the flow of bile into the stomach, for which its position seems to fit it. The intestine is short in *Anomia* and *Ostrea*, and exhibits various proportions up to twelve times the length of the

Fig. 17.
Cardium echinatum.

rise from the alimentary canal and from the superficial capillaries of the labial tentacles and generative mass, to the trunks receiving also the contents of the dilatable sinuses of the foot and peripheral part of the mantle, and pouring it into the median venous sinus, in which course it passes through the cavernous structure of the excretory (renal?) organ; the large sinus situated upon the posterior adductor and below the pericardium conducts the blood to the gills; but part of the veins of the mantle terminate, as Mr Garner first observed,¹ directly in the auricles. These, however, chiefly receive the blood from the branchial veins. Two semilunar valves regulate the flow of the blood from each auricle into the ventricle, and valves also prevent the reflux of the blood from the aorta into the ventricle. In *Arca*, *Lima*, and some *Pectunculi*, the ventricle is divided. Whenever the veins expand into sinuses they preserve a proper tunic. In *Ostrea* and *Anomia* the ventricle lies upon the rectum.

The gills (fig. 11, *p*, *p*) are essentially internal highly vascular folds of the pallial membrane, and are strengthened by series of delicate-jointed filaments, which support several rows of curved vibratile cilia. The respiratory currents are occasioned by the ceaseless action of these cilia, aided by that of the ciliated epithelium of the mantle, and are not dependent upon any opening or closing of the valves of the shell. The ciliary action is that likewise which brings the nutrient molecules to the mouth, chiefly along the marginal grooves of the branchial plates, where the molecules are mixed with mucus, and moulded into small filamentary masses.

In *Lucina* and *Corbis* there is only a single gill on each side; as a general rule there are two. Each gill consists of two membranous plates, continued into each other at the free margin of the gill; the contiguous plates of the two gills are continuous at the base or bottom of the branchial interspace where they are fixed, the basal border of the plate forming the opposite side behind the foot in the fresh-water mussels. The two plates of each gill are united together at pretty regular intervals in the direction of their breadth by transverse septa or bars, so as to include canals running transversely to the gill-plates. According to the course of the current of water through these interlaminar canals, they commence by the small slits or pores along the groove on the free margin in the branchial chamber, and terminate by the wider openings at the fixed margin of the gill in the anal chamber.

The minute particles suspended in the branchial currents

¹ Zool. Trans., vol. ii., p. 90.

Lamelli-
branchiata. are carried by the ciliary actions towards the mouth, and the water is filtered through the interlaminar canals before it escapes. The walls of the interlaminar tubes support a regular network of blood-vessels, longitudinal and transverse,—the latter being most prominent; the meshes are parallelograms, and form open spaces fringed internally by a narrow ciliated membrane. The cilia compel the requisite movements of the water in the branchial chamber when the Bivalve remains suspended in the air, as happens to a mussel attached to a rock above low-water mark. Even when the animal is in such a position as to be immersed only for about two hours in seventy-five days out of the year, it can live and grow, the retained water deriving oxygen from the atmosphere, and the animalcular food propagating therein. The life of the "tree oysters" (*Ostrea polymorpha*), suspended to the mangrove branches, is similarly explained through the wonderful mechanism of the ever-active microscopic cilia.

The two gills of one side are usually connected with those of the opposite side by their hind ends only, but sometimes the union is more extensive. In a few genera, as *Anatina* and *Pholadomya*, the two gills of the same side are so united as to appear like a single gill. In the *Pholadomya* this forms a thick oblong mass, finely plicated transversely, attenuated at both extremities, slightly bifid at the posterior one.

Although the microscopic cilia form the ordinary and constant dynamical part of respiration, the function is occasionally influenced by the muscles of the shell, as when the water is squirted out of the siphons by a sudden shutting of the valves. The quiet and ordinary respiratory current enters in *Anomia* at the anterior base of the shell, and escapes posteriorly near the termination of the branchiæ. In *Modiola vulgaris* the current enters by the cirrigerous border of the mantle, and between that part and the foot; it escapes by the posterior produced part of the mantle. In *Mactra* and *Telina*, when the conjoined siphons are extended, and the hyaline valve is exerted from the anal siphon, the current flows in at the "inhalent" branchial or ventral siphon (fig. 10, *g*), and rushes out by the "exhalent" dorsal or anal siphon (fig. 10, *g'*); there is no current at the pedal aperture. The branchial siphon is often much dilated, so that its diameter greatly exceeds the anal one,—*e.g.*, in *Pholas*. The siphonal apertures, especially the inhalent one, are provided with a circle of tentacles to prevent the ingress of noxious particles.

There is a remarkable plexus at the base of the gills, near the pericardium, which surrounds a distinct glandular organ in the higher Bivalves. It is double: each sac is elongated with glandular walls, and communicates with the pallial cavity by a small prominent orifice, usually close to the genital pores. The secretion of this body abounds with calcareous particles, and it was called by Poli the secreting organ of the shell. Modern analysis has detected uric acid in these sacs, and has thus determined them to be the renal organ.

An orifice at the extremity of the foot of *Solen*, at the middle of the foot of *Cardium*, and the tube situated above the pedunculate anus of *Pinna*, severally admit the sea-water into a reticulate system of channels in the substance of the foot, thence extending into the lobes of the mantles, and into a part of the visceral mass. By this provision for the admission of water the foot can be swollen out like a sponge, and made to exceed the capacity of the shell. The relations of this aquiferous system to the sanguiferous one are not satisfactorily determined. The fine jets of water expelled from the foot and the border of the mantle, when a *Solen*

is suddenly removed from the water, are from the aquiferous canals.

The nervous system of the *Lamellibranchiata* is here illustrated by the modification which it presents in the common mussel (*Mytilus edulis*, fig. 18).

The labial or subcesophageal ganglions *b* may be distinguished by their yellow colour. At the base of the labial processes they are connected by a short transverse chord *a*, passing dorsad, and in advance of the mouth. Four sets of

Lamelli-
branchiata.

Fig. 18.
Mytilus edulis.

filaments diverge from the labial ganglions,—*viz.*, the proper labial nerves, filaments to the hood-shaped process of the mantle above the mouth, nerves to the anterior adductor and continued into the circumpallial plexus *g*, and the principal nerve-trunks *b*, dividing or resolving on each side into the nerves to the pedial ganglion *v*, and those to the branchial ganglions *x*. The pedial ganglion completes the wide collar surrounding the cesophagus; it sends off nerves to the retractors of the foot, to the byssal ganglion, and to the acoustic sacs. The branchial or branchio-pallial ganglions *x* send off nerves which diverge as they pass to the base of their respective gills *c*; then each gives off a large nerve *g'*, which passes across the post-adductor muscle to the hinder part of the pallial lobe, along which it curves, and is continued forwards near the border of the mantle until it meets and anastomoses with the corresponding nerve *g*, which was continued over the ant-adductor from the labial ganglion. These circumpallial nerves *gg'* send off branches which form loops at the base of the pallial tentacles and along the rest of the free border of the mantle, forming the circumpallial plexus *hh'*, which is continued into the cardinal plexus *i*; such continuation being unconformable with the circumpallial nerve *gg'*.

Oysters are sensible of light: it has been observed that they closed their valves when the shadow of an approaching boat was thrown forward, so as to cover them, before

Lamelli-
branchiata.

any undulation of the water could have reached them. The Pecten has a number of sub-pedunculate ocelli (fig. 16) arranged round the inner margin of the mantle, whence Poli called the animal *Argus*. But the name is equally merited by some other Bivalves. As many as sixty ocelli have been counted on the convex lobe of the mouth, and ninety on the plain lobe, in *Spondylus gæderopus*.

The organ of hearing consists of a small sacculus, with thick transparent walls attached to the fore part of the pedial ganglion, and containing cretaceous sub-crystalline particles which perform oscillatory movements.

The labial tentacles seem well adapted, both by structure and position, in most Bivalves, to exercise the sense of smell; but in *Nucula* the palps are rigid. The mouth is highly susceptible of impressions from contact of its free, and commonly tentaculigerous border.

The nervous system in Acephalous Mollusks advances according to the complexity of their general organization, and especially of the muscular system.

To revert to the *Tunicata*, in a brief review of this progress and its chief physiological conditions, for which alone we have at present space:—The wants of the Ascidian are to breathe, to feed, to discharge its excrements, and emancipate its progeny. But the food is obtained by the same process as breathing, in this as in other Acephalous Mollusks; the streams of water which distribute oxygen over the surface of the vascular gill at the same time bring the nutrient particles to the mouth. This, moreover, begins at the œsophagus. There is no true mouth, no jaws, no teeth; for there is nothing to comminute or prepare for deglutition. In ourselves, when at rest, respiration is an involuntary or reflex action. It is accelerated by volition, to meet, perhaps, the exigencies of some violent locomotive effort; but locomotion is denied to the Ascidian. The same stimulus of necessity which in man is carried, during sleep, to the *medulla oblongata* by the *nervus vagus*, and which is reflected along the phrenic nerves, causing diaphragmatic action, independently of sensation or volition, is, we may suppose, similarly impressed upon and reflected from some analogous nervous centre in the Ascidian.

Ordinary respiration in this animal is, however, effected by an organization of which the actions seem to be less dependent upon a nervous centre than those of any of the peristaltically moving parts; the respiratory medium is renewed upon the vascular surface of the gill by the action of the vibratile cilia. Occasionally, at intervals, the sac may be seen unusually distended, and the water to be expelled by a sudden and forcible contraction of the mantle,—an act which may be compared with the involuntary yawn by which we distend our lungs to the utmost, and empty them by a violent expiration.

In the Ascidian the contents of the rectum and the generative organs are expelled by the same action of the mantle, though by a different outlet from that which gives passage to and fro to the respiratory currents. Both outlets are provided with feelers and sphincters, to prevent the entry of noxious bodies, and to regulate the exit of the excretory currents. The apparatus of nervous matter, in such a being, is a ganglion situated between the inhalent and exhalent orifices, as shown at fig. 5, *k*. Nervous filaments transmit to the ganglionic centre certain impressions; the requisite influence to cause contraction is reflected by other nerves to the muscular sac. But particles in the respiratory sac may be unfit for food, or hunger may require a greater or more frequent distension of that sac. Impressions are conveyed, therefore, from the mouth, or nutrient orifice, by nervous chords to the branchial gan-

glion; and, reciprocally, impressions received by the branchial ganglion are conveyed to the mouth.

Lamelli-
branchiata.

In the oyster the mouth is released from the respiratory sac; it is so placed as to have a wider field of choice. We now therefore find it provided with "labial processes," or organs for selection, if not prehension: hence the necessity for their possessing nervous centres of their own. But the oyster becomes fixed, like the Ascidian; there is no locomotion in the adult state. Expulsion of respiratory streams, and of the excrements and sperm-cells or ova, by sudden approximation of the valves, and contraction of the pallial lobes, is the sole sign of vigorous motion, and it produces the same effect as the contraction of the muscular tunic in the Ascidian. The stimulus to such action is reflected from the ganglion upon the adductor to that muscle, and to the muscles of the pallial border. Such ganglion is, therefore, analogous to, if not homologous with, the ganglion *k* in the Ascidian: it is the "branchial" ganglion; the superadded nervous centre is the "labial" one.

In the mussel, with the additional muscularity and fringed structure of the mantle-lobes, and with that further development of the whole muscular system which governs an increased activity of the breathing function, the "branchial ganglions" are increased and parted. The foot, which, besides guiding and fixing the byssus-threads, is an exploratory organ, calls for an additional centre of the nervous system—the "pedial ganglion." Bivalves are conscious of light, but cannot discern an approaching object. The movements of the predatory crab or insidious whelk, whether by day or night, upon the rock from which the mussel swings, produce vibrations that will affect an acoustic organ. The tip of the protruded foot may be the first part to receive their appulse, direct or reflected, from the parts of the shell to which it is affixed. Certain it is, that with the pedial ganglion (fig. 18, *v*) is associated that little sac, with prismatic oscillating otolites, which its discoverer Siebold and all subsequent physiologists hold to be a rudimental organ of hearing. The relations of this organ we shall find to change, in higher Mollusks, according as a ganglion may be situated near parts better adapted for the ready reception of the peculiar stimulus affecting it.

Thus the "pedial ganglion" is the third additional nervous centre in the Acephalous development. The fourth is where a small "siphonic ganglion" is developed at the point of confluence of the muscular respiratory tubes in the Bivalves which possess those accessory mechanical organs of respiration. The physiological explanation of this nervous centre is the same as that of the ganglion of the foot: the newly-developed parts extend and diversify the relations of the Bivalve with the surrounding world, and there must be corresponding centres for the reception and reflection of stimuli.

Take from man the necessity of clothing himself, by giving him a natural covering of scales or hairs, and you suppress, at the same time, all the arts which have attire for their object. Blunt his sense of taste, and the culinary arts must disappear; and so on for the other wants. Now, between the wants and the actions lie the faculties. The animals which have fewest organs have fewest wants, perform the fewest actions, and possess the fewest faculties. Hence the mystery which envelopes the psychical operations of animals is not so impenetrable as it seems.

The following table briefly expresses the principal characters of the soft parts upon which the Lamellibranchiate Bivalves have been divided and subdivided. It is based upon that given by Mr Garner in his paper upon the anatomy of this class of Mollusks,² with modifications suggested by subsequent observations of the writer and others:—

¹ The chief steps of this progressive development of the nervous system may be found described in Owen's *Lectures on Invertebrata*, 1855, p. 510-511.

² *Zoological Transactions*, vol. ii., p. 100.

Lamelli-
branchiata.Lamelli-
branchiata.

CLASSIFICATION OF THE LAMELLIBRANCHIATA.

MONOMYARIA, Lam. With but one adductor muscle.	Labial tentacles very long, not distinct from the branchiæ; branchiæ united; adductors subdivided, and with an adductor-like byssal muscle.....		ANOMIA—Placuna. OSTREA—Gryphæa.	
	Labial tentacles short, separate from the branchiæ.....	no foot.....	PECTEN—Pedom.	
		a foot.....	SPONDYLUS—Plicatula. LIMA.	
		branchiæ disunited medianly.....	foot long, cylindrical; ocelli at the edge of the mantle.....	
		branchiæ conjoined medianly.....	foot short, thick, with a disk at the extremity, from the centre of which depends a pedicellated oval body; ocelli.....	
	Mantle without separate orifices or tubes.....	foot slender, byssiferous; lips simple.....	foot compressed; no ocelli.....	
		foot long, rounded, deeply grooved, with a callosity.....	VULSELLA. AVICULA.	
		foot compressed, crescent-shaped; its margin undulated.....	ARCA.	
		foot oval below, its margin serrated; lips volute.....	PECTUNCULUS. NUCULA.	
	Mantle with a distinct anal orifice.....	foot small, byssiferous.....	TRIGONIA. MYTILUS.	
		muscles equal, two pairs of retractile muscles only; byssus rudimentary.....	byssus divided to its base..... byssus with a common common centre..... anus furnished with a long ligulate valve.....	
DIMYARIA, Lam. With two adductor muscles.	Mantle with an anterior and posterior orifice; not elongated into tubes.....	foot large, not byssiferous in the adult.....	MODIOLA. PINNA.	
		mantle widely open, { foot long, sickle-shaped..... foot very long, folded.....	LITHODOMUS. UNIO. CARDIUM. LUCINA.	
		mantle closed around the foot or byssus { foot short and discal, byssiferous; anterior muscle small..... foot small, cylindrical, bent at an angle; lips foliated.....	TRIDACNA. CHAMA.	
		foot long, sharp; lips simple.....	ISOCARDIA—Dicerias.	
	branchiæ not produced into the lower tube.....	tubes disunited; foot lanceolate.....	foot large, rather falciform; external branchiæ shortened; mantle tentacular; labial tentacles small, pointed.....	
		mantle more or less open in front...	foot moderate, tongue-shaped; external branchiæ shortened; edge of mantle simple; tentacles long, tapering.....	
		tubes more or less united; foot various...	PSAMMOBIA—Soletellina, &c. foot moderate; external branchiæ rudimentary; tentacles very large; margin of the mantle fringed.....	
		branchiæ united medianly.	TELLINA.	
	Mantle with two produced tubes, or siphons...	branchiæ disunited medianly.	tubes small, partially divided; foot very long, obtuse.....	
		tubes small; lips long.	CYCLOS—Cyrena, &c. tubes small, united to the extremity; foot large, heeled, and pointed.....	
		tubes long.	MACTRA. tubes large, united half-way; foot short and prominent behind....	
		foot long, club-shaped; tubes short.....	VENERUPIS. foot lanceolate; tubes small, united half-way.....	
	branchiæ produced into, or attached to the lower tube; tubes always united.....	mantle only open inferiorly for the protrusion of the foot.....	CYTHEREA. foot securiform; tubes larger and more or less distinct.....	
		mantle open anteriorly.	VENUS—Astarte, &c. foot small; branchiæ of each side united into one.....	
		foot very short, rounded	PANDORA. foot larger; branchiæ separate...	
		foot long, club-shaped; tubes short.....	CORBULA. foot not byssiferous; tubes large and coriaceous; lips long.....	
	mantle with a minute pedal opening anteriorly...	foot very small....	MYA. foot byssiferous; tubes moderate, lips short.....	
		shell cemented by one or both valves to the shelly tube.....	SAXICAVA. SOLEN—Sanguinolaria, &c.	

The *Monomyaria*, although they form an order or primary group of this class in most systems, are far from equivalent in the characters of their organization to the dimyaria group; and the same remark applies, though not with

equal force, to the binary division based upon the absence or presence of siphons or respiratory tubes. The quinary division of the class, as proposed by Cuvier, expresses more natural and equivalent groups. The classification here

Lamelli-branchiata. proposed is essentially that given in the writer's lectures on Invertebrata, 1855.

FAMILY I.—OSTREADÆ.¹

No anterior adductor; lobes of the mantle widely separated; foot none, or small and byssiferous. Shell inequivalve, sub-inequilateral; hinge, in some, edentulous.

Genera—*Anomia*, *Ostrea*, *Placuna*, *Pecten* (fig. 16), *Lima*, *Spondylus* (fig. 19), *Pedum*, *Plicatula*.

Of this family, the oyster (*Ostrea edulis*)—the most valuable of British Bivalves—may be regarded as the type.

From the time of the discovery of Britain by the Romans the flavour of the oyster has been held in high esteem. The species is gregarious, and forms banks, usually on a rugged rocky bottom of from 5 to 20 fathoms depth, where they are obtained by the dredge. When collected with a view to the market, they are usually transferred to artificial grounds in shallow water, where they increase in size, but more tardily than in their native beds, not becoming full-grown until from five to seven years; neither do they breed so freely, and they are liable to fatal effects from severe frost. They, however, "fatten," as it is called, and acquire a more delicate flavour. The "close" or spawning season is in May and June; the season for sale and distribution in London is from the 4th of August to the 12th of May inclusive. About 30,000 bushels of "natives," or oysters from artificial beds, and about 100,000 bushels of sea-oysters, are annually sent to the London market. The western coast of Scotland and the Hebrides offer conditions peculiarly favourable for the propagation and perfection of the edible oyster. In the artificial beds, which thrive best in sheltered bays and estuaries, the oysters sometimes acquire a green colour. On close examination, the colour is seen to be confined to particular parts. The branchiæ and the intestinal canal beyond the stomach, *e.g.*, are of a bright green; the liver is of a blackish-green instead of its usual reddish tint. The heart, nerve-ganglions, adductor-muscle, and mantle retain their normal colours. The above partial coloration is conjectured to be due to *Confervæ* or green monads in the breeding tanks.

Fig. 19.
Spondylus varius.

FAMILY II.—AVICULIDÆ.²

A very small anterior adductor; mantle lobes separate; foot small, byssiferous.

Genera—*Avicula*, *Meleagrina*, *Malleus*, *Vulsella*, *Ger-villia*, *Perna*, *Crenatula*, *Inoceramus*, *Pinna*.

In this family the "hammer-oysters" (*Malleus*) are most remarkable for their form; the pearl-oysters (*Avicula*) and *Pinna* most attractive on account of their products.

The *Avicula* with shells less oblique in form, and with flatter and more equal valves, showing the posterior pedal impression blended with that of the great adductor, constitute the subgenus *Meleagrina*, of which the proper "pearl-oyster" (*Mel. margaritifera*) is the most valuable species, on account of the nacre and pearls which it produces. The "nacre," or "mother-of-pearl," is the iridescent, pearl-like, inner layer of the shell. For this substance, which is used largely in ornamental manufactures, immense numbers of the "pearl-oyster" are annually imported: the "silver-lipped" variety from the Society Islands, the "black-

lipped" from the Philippines, and a smaller kind from Lamelli-Panama. These fetch from L.2 to L.4 per ton. The nature of "pearl" has been already defined. The pure pearl of commerce is generally spherical, and has a yellowish-white or bluish colour, with a peculiar iridescent lustre. Its hardness is due to carbonate of lime, which dissolves with effervescence in acid, leaving fine films of membrane. Such pearls bore an almost fabulous price with the ancient Romans; their greatest naturalist testifies:—"Principium culmenque omnium rerum pretii, margaritæ tenent." (*Plin. Hist. Nat.*, lib. ix., c. 35.) In modern times their value has declined. A handsome necklace of Ceylon pearls, in size less than a large pea, may fetch from L.170 to L.300; the single pearls selling at about a guinea each. Pearls of the size of peppercorns sell at from 2s. 6d. to 10s. Pearls of still smaller size are called "seed-pearls." They are mostly sent to China. A pearl, pear-shaped, regular, and said to be without blemish, nearly 3 inches in length, and two-thirds of an inch in diameter, brought up at Catifa in Arabia, and now in possession of the Shah of Persia, has been valued at L.10,000. Mr Hope's pearl, exposed to view at the "Great Exhibition" of 1851, measures 2 inches in length, 4 inches in circumference, and weighs 1800 grains.

The best pearl-forming pearl-oysters are brought up from about 12 fathoms in the Persian Gulf, off the west coast of Ceylon, in the straits of Malacca, and at Tuticorin on the Coromandel coast. The largest pearls are found in the deepest places, as at the island Kharrak in the Persian Gulf. The Persian pearls are more esteemed than those of Ceylon. The pearl fishery of Tuticorin is monopolized by the East India Company, and that of Ceylon by the government; but it is very doubtful whether the results justify these exceptions to the general laws of political economy.

The animal of the *Pinna*, called *Chimera* by Poli, is remarkable for the abundance, length, fineness, and lustre of the filaments composing the "byssus." The part so called exists in many Bivalves; but in some it is peculiar to an early period of life; in none does it attain so great a development as in *Pinna*. The byssus-filaments are united towards their roots into a common mass; they are attached in a cavity at the base of the foot by a peculiar substance secreted there (conjunctive matter). From the cavity a furrow runs to nearly the extremity of the foot, and along this furrow is situated the glandular tissue by which the byssus is secreted. Réaumur maintained that these horny threads were spun just like the web of caterpillars and the nets of spiders. With the assistance of the muscular foot, these threads are directed to determinate situations, and caused to adhere there firmly by their broad disciform extremities; they grow again if cut off.³

The byssus serves as an anchor to the Bivalve, of which use the common mussel offers a familiar instance. Vigorous strokes of the hatchet are needed to divide the byssus in detaching the great clam or "benitier" shell (*Tridacna*) from the rocks. The silky byssus-threads of the *Pinna nobilis* are woven into gloves and stockings in Sicily and Calabria; but they are objects rather of curiosity than of daily use.

FAMILY III.—MYTILIDÆ.

A small anterior adductor; mantle lobes united between the branchial and anal slits; foot cylindrical, grooved, byssiferous. Shell equivalve; hinge edentulous.

Genera—*Mytilus*, *Modiola*, *Lithodomus*, *Crenella*.

The common mussel (*Mytilus edulis*) is the most important member of the present family in regard to human food. Mussels are gregarious, in extensive beds, always uncovered at low water; they are as widely distributed as

¹ Lat. for "oyster."

² A. Mueller de Byssu *Accephalorum Accad.*, Tab. ii. Berolini, 1836, 4to; and in Wiegmann's *Archiv.* 1837, §§ 1-39, Tab. i., ii.

³ Lat., signifying a "little bird."

Lamelli-branchiata. the oyster, and more easily attainable. The flesh is most esteemed and is least unwholesome in autumn; in spring, during the spawning season, cases of the gastric affection, followed by cutaneous eruption, called "musseling," are most common. They are, however, sufficiently exceptional to permit an immense consumption of this mollusk. It is estimated in Edinburgh and Leith at 400 bushels—say 400,000 mussels—annually; still greater numbers are collected for bait in the deep-sea fisheries. The species thus affords employment to numerous women and children of the fishing villages, especially along the Frith of Forth.

A singular form of fresh-water mussel (*Mytilus polymorphus*, Lam.), a native of the Aralo-Caspian rivers, is supposed to have been introduced with foreign timber into the Surrey Docks, where it was observed by Mr J. de C. Sowerby in 1824. It has since spread into canals, and has established itself as a British species. The anal and branchial slits are a little produced—the latter like a short siphon; and the rest of the mantle is closed, save at a small aperture through which the foot and byssus protrude. Accordingly, this mussel has been separated generically from *Mytilus*, as *Dreissena*, and under other names; and the *Dreissena polymorpha* departs widely from the pallial characters of the family Mytilidæ.

In most dimyary Bivalves the foot is an organ of locomotion. To some which rise to the surface of the water it acts, by its expansion, as a float; to others it serves, by its bent form, as an instrument to drag them along the sands; to a third family it is a burrowing organ; to many it aids in the execution of short leaps. In the piddocks (*Pholas*), two strong muscles are sent from the foot to be attached to the rough spatulate terminations of the bent processes under the beaks of the valves; these serve as fulcra in the excavating actions of the foot.

We may generally observe, in relation with the greater development and more active function of the foot, a corresponding complexity of the respiratory system. This is effected by the superaddition of accessory organs in the form of tubular prolongations of certain parts of the margin of the mantle, which are provided with a special development of muscular fibres. These are called "siphons" (fig. 11, *g*, *g'*).

FAMILY IV.—ARCADÆ.

Anterior and posterior adductors subequal; mantle-lobes separate; foot large, bent, deeply grooved. Shell equivalve; hinge long, multidenticulate.

Genera—*Arca*, *Cucullæa*, *Pectunculus*, *Limopsis*, *Nucula*, *Isoarca*.

The animal of the *Yoldia* of Müller, otherwise nearly allied to *Isoarca*, departs from the pallial characters of the family in having the branchial and anal openings distinct, and produced into short retractile siphons. It makes a transition to the next family.

FAMILY V.—SOLENELLIDÆ.

Mantle-lobes united behind with a single siphonal orifice or retractile siphon. Shell equivalve.

Genera—*Solenella* (foot deeply cleft, hinge with fine sharp teeth); *Solemya* (foot probosciform, hinge edentulous).

FAMILY VI.—TRIGONIADÆ.

Mantle-lobes separate; foot long, pointed, sharply bent. Shell equivalve, trigonal; hinge-teeth few, diverging.

Genera—*Trigonia*, *Myophoria*, *Axinus*, *Lynodesma*.

Of *Trigonia* only three living species or varieties are known; they are peculiar to Australia. Upwards of one hundred extinct species have been defined from fossil shells, ranging from the Trias to the Chalk, in Europe. It is remarkable that no species of *Trigonia* has been found in the Tertiary deposits of that continent.

FAMILY VII.—UNIONIDÆ.

Mantle-lobes united between the siphonal orifices and, rarely, in front of the branchial opening; foot very large, tongue-shaped, compressed, byssiferous in the fry. Shell usually equivalve; anterior teeth thick and striated; posterior ones laminar, sometimes wanting.

Genera—*Unio*, *Castalia*, *Anodon*, *Iridina*, *Ætheria*, *Mülleria*.

The common fresh-water mussels (*Anodon*), and the river mussels (*Unio*), exemplify the present family. To the latter genus belongs the pearl-forming species (*Unio pictorum*, Lam.; *Mya margarifera*, Linn.) of many of the rivers of Scotland. The family arrives at its maximum in regard to species and individuals in the large rivers and lakes of North America, and has furnished the subjects for the beautiful monographs by Mr Isaac Lea and Mr Kirtland in the *Transactions of the American Philosophical Society*, 2d series, vols. iii. and iv. (on the *Naiadæ* and species of *Unio*). In most of the Bivalves of the present family the fry are hatched in one of the gills, which swells out to such a size as to require a particular space in the shell for their lodgment; and the valves of the female are consequently more convex than those of the male.

The following dimyary families have short siphons and the pallial line simple:—

FAMILY VIII.—CHAMIDÆ.

Pedal orifice small; foot very small. Shell inequivalve; hinge-teeth 2—1 (two in one valve, one in the other).

Genera—*Chama*, *Monopleura*, *Diceras*.

The species of the latter genus are extinct, and characteristic of the Middle Oolites. The shell is remarkable for the much-produced spiral umbones or beaks, which give the valves the appearance of rams' horns.

FAMILY IX.—HIPPURITIDÆ.

(Order *Rudistes*, Lam.)

All the genera are extinct. The best illustration of their nature and affinities is given by Mr Woodward.¹

FAMILY X.—TRIDACNIDÆ.

Pedal orifice large; siphonal orifices surrounded by a thickened pallial border, the anal one with a tubular valve; foot small, cylindrical, byssiferous. Shell equivalve, open; muscular impressions sub-central and blended.

Genera—*Tridacna*, *Hippopus*.

In this family the Lamellibranchiate type of organization is manifested under its largest size. The valves of *Tridacna gigas* are accordingly used to ornament gardens, as basins for fountains, and in Romanist churches for holding the holy water. The two large valves for this purpose in the church of St Sulpice at Paris measure each two feet in breadth. Linnæus records a shell in the "Museum Ludovicæ Ulricæ" which weighed 532 pounds.

Hippopus maculatus, or the "bear's-paw clam" of dealers, is perhaps the most beautiful of Bivalves, whether in regard to form, texture, or colour.

FAMILY XI.—CARDIADÆ.

Pedal orifice large; siphons usually short; foot large, sickle-shaped. Shell equivalve, cordiform; cardinal teeth 2, lateral teeth 1—1, in each valve.

Genera—*Cardium*, *Hemicardium*, *Lithocardium*, *Serripes*, *Adacna*, *Conocardium*.

The rapid Mollusk called cockle (*Cardium edule*) exemplifies the present family. It affects and often abounds in sandy bays, near low water. On the recess of the tide it burrows a few inches below the surface, its place being marked by a small depression. Women and children dig

¹ On the Structure and Affinities of the Hippuritidæ, *Quarterly Journal of the Geological Society of London*, February 1855.

Lamelli-branchiata. up the shell-fish with a piece of crooked iron or a narrow shovel. They are in season during March, April, and May.

FAMILY XII.—LUCINIDÆ.

Mantle usually widely open below, with one or two siphonal apertures; foot long, cylindrical or ligulate, sometimes byssiferous. Shell orbicular, closed; hinge-teeth 1 or 2, lateral teeth 1—1, or obsolete.

Genera—*Lucina*, *Corbis*, *Ungulina*, *Kellia*, *Montacuta*, *Lepton*.

FAMILY XIII.—CYCLADIDÆ.

Mantle open in front; siphons more or less united; foot large, tongue-shaped. Shell sub-orbicular, closed; hinge with cardinal and lateral teeth.

Genera—*Cyclas*, *Cyrena*, *Pisidium*.

The species of this family live in fresh or brackish water. The fry of *Cyclas* are hatched in the internal gill.

FAMILY XIV.—ASTARTIDÆ.

Mantle-lobes united behind by a curtain pierced with two siphonal orifices; foot thick or compressed, tongue-shaped. Shell equivalve, closed; cardinal teeth 1—3, and usually a lateral tooth in each valve.

Genera—*Astarte*, *Circe*, *Cyprina*,¹ *Crassitella*, *Isocardia*, *Cypricardia*, *Cardita*.

In the following families the siphons are long and retractile, leaving a sinuous "pallial line":—

FAMILY XV.—VENERIDÆ.

Mantle with a rather large anterior opening; siphons unequal, more or less united; foot tongue-shaped, compressed, sometimes grooved and byssiferous. Shell regular, closed; hinge with usually three diverging teeth in each valve.

Genera—*Venus*, *Cytherea*, *Artemis*, *Lucinopsis*, *Venerupis*, *Petricola*, *Glaucomya*.

"The shells of this tribe are remarkable for the elegance of their forms and colours; they are frequently ornamented with chevron-shaped lines. Their texture is very hard, all traces of structure being usually obliterated. The *Venerida* appeared first in the Oolitic period, and have attained their greatest development at the present time. They are found in all seas, but most abundantly in the tropics." (Woodward).

FAMILY XVI.—MACTRIDÆ.

Mantle more or less open in front; siphons united with fringed orifices; foot compressed. Shell equivalve, trigonal; hinge with two diverging cardinal teeth, and usually with lateral teeth.

Genera—*Mactra*, *Gnathodon*, *Lutraria*, *Anatinella*.

FAMILY XVII.—TELLINIDÆ.

Mantle widely open in front; foot tongue-shaped, compressed; siphons separate, long and slender. Shell usually equivalve and closed; cardinal teeth not exceeding 2, lateral teeth 1—1, sometimes wanting.

Genera—*Tellina*, *Psammobia*, *Sanguinolaria*, *Syndosmya*, *Scrobicularia*, *Mesoderma*, *Donax*.

In the following families the mantle is sheath-shaped, closed, save at the pedal and siphonal apertures. The group answers to the "Enfermés" or *Inclusa* of Cuvier. The species are burrowers in sand, mud, wood, or stone:—

FAMILY XVIII.—SOLENIIDÆ.

Siphons short and united (in the long-shelled genera), long and partly separate (in the shorter and more compressed genera); gills prolonged into the branchial siphon; foot large, sub-cylindrical. Shell gaping at both ends.

Genera—*Solen*, *Cultellus*, *Machæra*, *Solecurtus*.

The "razor-shells" or "spout-fish" (*Solen siliqua* and *Solen curtus*) exemplify the present family. They are used in many places as food. Their burrows at low water are indicated by a small orifice like a key-hole, and they are found a foot or two beneath the surface. It is said that they never voluntarily quit their burrows; but fishermen in quest of them have the habit, in some localities, of throwing a pinch of salt in their holes, when they speedily rise to the surface, and are hooked out by a bent iron. If permitted, they soon bury themselves again. When used as bait for haddock or cod, the "razor-fishes" are kept for a day or two.

FAMILY XIX.—MYACIDÆ.

Siphons united; foot small. Shell gaping behind.

Genera—*Mya*, *Corbula*, *Neera*, *Thetis*, *Panopæa*, *Saxicava*, *Glycimeris*.

The "gapers" (*Mya arenaria* and *Mya truncata*) exemplify the present family. They are found from a few inches to a foot below the surface, in mud or shingle. They are eaten in the Hebrides and in Zetland; and are collected for baits by fishermen.

FAMILY XX.—ANATINIDÆ.

Siphons long, more or less united; foot very small. Shell often inequivalve.

Genera—*Anatina*, *Pholadomya*, *Lyonsia*, *Pandora*, *Myochama*, *Chamostrea*.

The "lantern-shells" (*Anatina rostrata* and other species) exemplify this family. *Pholadomya* has an external ligament only; the gills are compacted into a single mass on each side, and the mantle has a fourth opening for a supplemental rudiment of the foot.

FAMILY XXI.—GASTROCHÆNIDÆ.

(*Tubicolidae*, Lam.)

Siphons long, united to near their free ends; foot finger-shaped, sometimes grooved and byssiferous; mantle with a boring disc in front. Shell regular, wedge-shaped, gaping in front; in some more or less cemented to a superadded calcareous tube.

Genera—*Gastrochæna*,² *Clavagella*, *Aspergillum*.

"The *Gastrochæna modiolina* perforates shells and lime-stones; its holes are regular, about 2 inches deep and $\frac{1}{2}$ inch diameter; the external orifice is hour-glass shaped, and lined with a shelly layer, which projects slightly. When burrowing in oyster-shells it often passes quite through into the ground below, and then completes its abode by cementing such loose material as it finds into a flask-shaped case, having its neck fixed in the oyster-shell." (Woodward.) In the *Gastrochæna numia*, Spengl. (*Fistulana clava*, Lam.), from the coast of Coromandel, the tube is free, and grains of sand often adhere to it; other species burrow in madre-pores, and their calcareous breathing-tube is elongated to keep pace with the growth of the Polypes.

The "water-pot shells" (*Aspergillum*), and the "club-shells" (*Clavagella*), inhabit each an elongated tube, the extremities of which correspond to the anterior and posterior ends of the animal's body. The posterior end is widely open, expanding in a foliated form in the open sea; the opposite end communicates, by a varying number of minute and often-branched tubes, either with the interstices of a sandy bed, as in *Aspergillum*, or with cavities in the sandstone or coral rock in which *Clavagella* is more commonly found imbedded.

From the greater resistance, therefore, which the nidus of *Clavagella* presents to the development of the anterior tubes, these are less regular both in the number and place

¹ This Lamarckian name is too like the Linnæan *Cyprinus*; the name of the family, which ought to be retained for the use of Ichthyology exclusively, is accordingly here changed.

² Gr., in reference to the front or ventral gaping of the shell.

Lamelli- than in *Aspergillum*; their formation being influenced by
branchiata. the proximity to the tube of other cavities in the rock.

Where these tubes have been developed from nearly the whole of the surface of the mantle which intervenes to the wide aperture of the shell, the specimen of *Clavagella* has been termed *echinata*, though these processes are not closed and pointed at the extremity, as might be implied by Lamarck's trivial denomination; where, on the contrary, their formation has been limited to the anterior part of the mantle, the specimen has been raised to the dignity of a species by the term *coronata*. *Clavagella*, like its congener *Gastrochaena*, is remarkable for the wide opening of the valves. These cannot in the natural state be brought into opposition on their ventral margins; they are unequal to the protection of the soft parts; and hence the necessity of the extraneous defence which the walls of their rocky chamber afford them, these walls being also lined to a greater or less extent with a calcareous exudation from the mantle. Yet a specific character has been seized from this disposition of the valves, indicated by the species called *Clavagella aperta*. The soft parts of *Clavagella*, when exposed by the removal of the free valve and outer layer of the mantle, present the appearance shown in fig. 20. The true foot is wholly concealed by the great development of the muscular margin of the mantle. The extremities of the labial tentacles *n* protrude at the interval between the anterior adductor *g*, and the retractor of the siphon. The relative position of the soft parts (fig. 20) to the dwelling-chamber (fig. 15) is as follows: The mouth is turned towards the closed end of the chamber *a*, which is the anterior part; the heart and rectum are nearest the side where the valves are connected by the ligament *b*, or the dorsal part; the visceral mass projects towards the opposite or ventral side *c*, while the siphon extends into the commencement of the calcareous tube *d*, which leads out of the anal or posterior part of the chamber. The fixed valve (fig. 15) which covers the rough surface of the porous rock or coral like the tiling of a chamber floor, and affords a smooth, polished surface for the support and attachment of the animal, is the left valve; the right valve (figs. 21, 22) remains free, or is connected only to the soft parts and cardinal ligament, in order to assist in the excavating and respiratory actions.

That these actions are of a powerful kind is to be inferred from the remarkable development of the muscular system in the *Clavagella*. The impression of the great or posterior adductor (fig. 22, *f*) is carried two lines beneath the surface of the chamber posteriorly, but gradually rises to the level of the valve. The impression of the smaller anterior adductor (fig. 22, *g*) is fainter, and is continued into the sinuous pallial impression which follows the contour of the anterior margin of the valve at about two lines' distance from it. In the free valve (fig. 22) the last two muscular impressions are separate.

The shelly substance of the fixed valve passes without interruption into that of the tube; a slight ridge circumscribing the entry of the tube into the chamber may be regarded as the line of separation, unless the extent of the valve be limited to that of the internal nacreous deposition.

Fig. 20.
Clavagella aperta.

Fig. 21.
Free valve (*Clavagella aperta*).

The area of the tube is of an oval form. The calcareous Lamelli-
parietes are 1-50th of an inch in thickness at the outlet of branchiata.
the tube, and about 1-30th at the opposite extremity.

The free valve (figs. 21 and 22) is an unequal triangle, with the angles rounded off, about the thickness of a sixpence, moderately concave towards the soft parts, striated only in the direction of the layers of increment on the outer surface. The layers of increment of the free valve gradually increase towards the dorsal edge for a little more than one-half of the valve, beyond which the layers continue of almost equal breadth. Free valve (*Clavagella aperta*). This growth of the valve corresponds to the direction in which the chamber is enlarged, which is principally on the dorsal, dextral, and anterior sides. Now this is the mode of enlargement best adapted for the full development of the ovary; so that it would seem that the *Clavagella* continues for a certain time to work its way into the rock without material increase of size, leaving behind it a calcareous tube which marks its track, after which it becomes stationary, and limits its operations to enlarging its chamber to the extent necessary for the accomplishment of the great object of its existence.

Fig. 22.
Free valve (*Clavagella aperta*).

The mantle envelopes the body like a shut sac, but is perforated for the siphon and foot, the opening for the latter being reduced to a small slit marked by the insertion of a bristle in fig. 20, which serves to keep up a communication between the chamber and its inhabitant; and it is seen that the chamber has always a communication with neighbouring cavities in the rock by means of the calcareous tubules, the formation of which is determined by the proximity of those cavities. When therefore the *Clavagella*, by a sudden contraction of its adductor muscles (fig. 20, *f*, *g*), has forcibly expelled the branchial currents from the siphon, the space between the free valve and the walls of the chamber would be simultaneously filled either by water rushing in through the tubules or forced out from the branchial cavity through the small pedal orifice of the mantle.

The outer dermoid layer of the mantle is extremely thin, and where it does not line the valves, it is mottled with minute dark spots, and presents a glandular appearance under the microscope. The muscular layer, after forming the siphon and its retractors, is confined to the anterior part of the mantle, where it swells into a thick convex mass of interlaced and chiefly transverse fibres attached to the valves along the sinuous submarginal depression above mentioned, and forming one of the principal instruments in the work of excavation. No fibres could be detected in other parts of the mantle, nor could any longitudinally radiating muscles be expected in a mantle which had no lobes to be retracted.

The siphon, in the contracted state which it presented in the specimen dissected by the writer, formed a slightly compressed cylindrical tube half an inch in length, and the same in the long diameter. It is traversed longitudinally by the branchial and anal canals, which are separated from each other by a muscular septum extending to the end of the siphon, beyond which the two tubes do not separately extend outwards. The inner extremity both of the anal and respiratory tube is provided with a valvular fold. Their terminations are beset with short papillæ. The retractor muscles attach the siphon to the posterior adductor on one side, and to the anterior extremity of the oval mass of muscular fibres above mentioned on the other, leaving an intermediate space on both sides of the body, which exposes part of the gills and labial tentacles. The muscular mass which bounds the anterior part of the animal's body is of an oval form, 1 inch 3 lines in length, 8 lines in breadth,

Lamelli-
branchiata.

and varying in thickness from 2 to 3 lines. It is smooth and convex externally, and hollowed out within to lodge the viscera at the base of the foot, for the passage of which it leaves the small orifice above mentioned. The margins attached to the valves are more or less irregular; that which is affixed to the loose valve is the broadest, being at the ventral extremity 3 lines in breadth; it may here be regarded as a third adductor. Posteriorly it is continued into the small adductor muscle. This muscle is marked *g*, the great or posterior adductor *f*, in fig. 20.

The ovary is of a gray colour, forming a mass at the dorsal aspect of the body above the great adductor muscle, and extending ventrad on either side the cesophagus and stomach to the opposite end of the base of the foot.

All this mass of intestinal folds, hepatic follicles, and ova, was covered by a thin membrane. The little muscular process or foot which passes through the anterior slit of the mantle is but 4 lines long and half a line in breadth.

The organization of *Clavagella*, like that of *Aspergillum*, described in the *Reise von Afrik* of Dr Rüppell, is thus seen to be modelled on the Lamellibranchiate type, and follows most closely, in the variations from that type, the modifications which have been observed in *Gastrochaena*.

The lengthened worm-like figure of *Aspergillum* is exchanged in *Clavagella* for a shorter form, with greater lateral development; and instead of the small rudimentary valves, which are incised, as it were, in the calcareous sheath of *Aspergillum*, we find them here largely developed, and one of them always remaining at liberty to be applied by a powerful muscular apparatus to those offices which are essential to the forcible expulsion of the fluid in the branchial cavity.

The *Aspergillum* exhibits the most extreme modification of the true Bivalve type of shell by the complete coalescence

serve as little any ordinary final purpose as the teeth buried in the gums of the foetal whale.

Lamelli-
branchiata.

The larger end of the tube is pierced by a number of short and small tubules and by a minute central fissure; the opposite or siphonal end is open, it is either plain or ornamented by circular plicated outstanding plaits formed by the shell-secreting layer of the siphons, and indicative of successive phases of growth of the tube.

The *Aspergillum vaginiferum* (fig. 23) inhabits the Red Sea; other species have been found in Java, Australia, and New Zealand.

FAMILY XXII.—PHOLADIDÆ.

Animal clavate or vermiform; siphons large, long, united nearly to their ends; foot short, truncate. Shell gaping at both ends; hingeless, with sometimes accessory valves, or a supplementary tube and palettes.

Genera—*Pholas*,¹ *Xylophaga*, *Teredo*, *Teredina*.

The piddocks (*Pholas*) perforate all substances that are softer than their own valves. The mantle extends over the hinge, and, in *Pholas dactylus*, develops two accessory plates to protect the umbonal muscle, and a small transverse plate behind; a long unsymmetrical plate fills up the dorsal interspace of the valves behind the hinge. The prominent parts of the valves are beset with calcareous inequalities, connected by fine transverse parallel ridges, roughening the outer surface like a rasp. This species is used for food in Scandinavia, and for bait in the south of England; the hyaline style, lodged in the translucent foot, is worthy of note in the recent animal. The common piddock is gregarious. Fig. 24 shows a block of stone perforated by the

Fig. 23.
Aspergillum vaginiferum.

of its valves (fig. 23, *a*) with the parietes of the shelly tubes. They there form the stamp of its true affinities, but sub-

Fig. 24.
Pholas dactylus.

Pholas dactylus: the breakwater at Plymouth is thus infested.

In *Pholas dactylus* the labial processes are relatively longer than in *Pholadomya*, but are equal, and both have the usual transversely-plicated structure, although the outer one adheres by a great part of its outer surface to the mantle. In the *Pholas crispata* the whole external surface of the labial process is adherent, but it retains the fine plicated membranous structure; the internal labial process is a thick, broad, scarcely flexible mass, convex outwardly, concave where it is closely applied to the visceral mass, of a soft parenchymatous structure, quite smooth on the con-

¹ Gr. verb, "to be hid in a hole."

Lamelli-branchiata. cave side, with hardly perceptible traces of the transverse lineations on the convex surface. This condition of the inner labial process has not been found in other Bivalves.

The ship-worms or pile-worms (*Teredo navalis*) live in wood, which they perforate in the direction of the grain, save where a knot in the timber or the tube of another *Teredo* is met with. The cavity in which they reside is lined with a calcareous incrustation. They grow in the wood, and do not first enter it as adult animals, for the external aperture, towards which the two tubes (palettes) are turned, is too narrow to allow the inclosed animal to enter. In fig. 25 the small valves of the true Bivalve shell are shown at *a*; the foot, which with the valves constitutes

Fig. 25.
Teredo navalis.

the boring organ, is shown at *c*; *d* is the liver and alimentary canal; *e* the branchiæ; the siphon-tubes and "palettes" terminate the vermiform body, and always point to the outlet of the burrow.

For the distinction of species recourse is had, amongst other characters, to the form of the two small shovel-shaped calcareous plates at the base of the siphons, commonly named *palettes* or *palmulae*. One species, famous for the injury it caused to the piles of the dykes in Holland, in the beginning of the last century especially, is referred by some Dutch naturalists to the *Teredo Sellii* (*Teredo navalis*, L. et auctor. in part, *Teredo batavus*, Spengler). It is figured in the work of Sellius, and in Blumenbach, *Abh. naturhistorischer Gegenstände*, No. 89. The palettes are fixed on a short pedicle, inversely triangular, and terminating at the broad end on each side in a point. Piles that had been driven only six or seven weeks previously were seen to be entirely eaten through by this worm, and robbed of all their strength. In this way the island of Walcheren was in 1730 threatened with destruction. From time to time the same mischief was discovered in other places, especially on the Zuiderzee near Medemblik, Lambertshagen, &c.; West Friesland was forced, in consequence, to mask its dykes with large stones, which, being brought into the country from abroad, occasioned a great expense. Since the middle of the last century the mischief has much diminished. Copper-sheathing and broad-headed iron nails have been found most effectual in protecting ship-timbers and piers from the ravages of this singular little Bivalve. An excellent account of the pile-worm is given in the work of G. Sellius, *Histor. nat. Terebinis*, Traj. ad Rhen. 4to. Fossil *Teredines* are found in the Tertiary and Chalk strata.

The phenomena of boring substances of different kinds and densities by the Bivalve Mollusks have been the subject of many observations and experiments, and have suggested many hypotheses.

The peculiar shape and development of the foot in the *Solen* and other "burrowing" Bivalves, might have led to its recognition as an excavating agent, if even it had not been seen to effect the purpose in the living Mollusk. Direct observation of the "boring" Bivalves in the act of perforation has been rarely enjoyed, and the instruments have been more frequently guessed at or judged of from the structure of the animal. The peculiar shape, great strength, and restricted size of the concentrically-ridged valves, the disproportion size and strength, and the red

colour of their adductor muscle, with the curved unibonal processes for its advantageous leverage, in the *Teredo navalis*, could not fail to attract the attention of the unbiassed observer to their adaptation for the function of excavating wood.¹ It indicates a mind unfitted for physiological discovery to deny this adaptation, because the exterior of the valves is sometimes coated by a dried layer of the abundant mucus which is exuded from the pedial aperture during the active movements of the borer. The rasp-like exterior of the shell of the *Pholas crispata*, with the modifications of the adductors and their fulcral apophyses, in like manner suggests the rasping rotatory action by which the valves may produce, or aid in producing, the burrows in the rocks in which the piddocks conceal themselves. To deny this use of the *Pholas* shell because the shell of some other rock-boring Bivalve is smooth, is another inconsequential deduction. There are, doubtless, other modes of boring besides the shell-action; but the recognition of any such need not involve a negation of every mode save the one so recognised.

Mr Osler² has advocated the hypothesis of a chemical solvent as the boring agent, but such solvent has not been demonstrated; and the necessity of its being applied in currents of water to calcareous rocks on which alone it could operate, with the liability of the shell of the animal secreting the solvent to be affected thereby, have been insuperable obstacles to the acceptance of the hypothesis.

Mr Garner³ has called attention to the streams generated by the extensive surface of ciliated epithelium in the Lamellibranchs, as probable aids to the rasping action of the valves; and since this demonstrated and constantly acting dynamic causes as unceasing a current of water in the holes of the borers, the non-extension of such current between the shell and the rock, where they may be in close contact, is no argument against the influence of the current in the rest of the hole, and especially at the line where it is opposed by such contact. The ingenious idea of the ciliary action as an accessory power in boring may therefore be accepted; from its universal applicability it is, at least, certainly worthy of notice.

The writer of the present article many years ago suggested that the same kind of instrument might be applied by Bivalve Mollusks to boring in rock which had been recognised as the one used for boring in sand. The anatomy of the *Clavagella* offered many points highly suggestive of the inadequacy of the hypotheses of the burrowing agents promulgated at the time when that lithodorous Bivalve was first dissected; and its structure indicated a power that had not been previously suspected in rock-borers. In the first place, it was evident that the valves could not act, as they do in *Teredo* and *Pholas*; for the terminal expansion of the chamber (fig. 15) had an irregular elliptical form in transverse section; and, moreover, one valve was fixed so as to form the lining-plate of its side of the chamber. The animal dissected (*Clavagella lata*) had formed its chamber in a rock of calcareous grit; but a nearly allied species (*Clav. australis*) had bored its way into siliceous grit; whilst specimens of *Clavagella melitensis* were ensconced in argillaceous tufa.⁴ A special solvent for each species greatly complicates the chemical hypothesis. The muscular layer of the mantle of the *Clavagella aperta* presented, however, a peculiar modification, being expanded into a thick convex cushion (fig. 20, *l*), where it was applied to the bottom of the chamber, through the development in its substance of a mass of interlaced muscular fibres. The last excavated part of the chamber was, as it were, moulded to the sur-

¹ In the great *Teredo arenaria*, which lives in soft mud, the valves are wanting, according to Dr Gray; or their homologues form the convex cap closing the periodical growths of the calcareous tube.

² On the Burrowing and Boring Marine Animals, *Philosophical Transactions*, 1826.

³ On the Anatomy of the Lamellibranchiate Bivalves, *Zoological Transactions*, vol. ii., 1839.

⁴ All these rare species were liberally confided for examination to the writer by Mr H. Cuming.

Lamelli-branchiata. face of the cushion, which was perforated by a minute slit for the occasional passage of a filamentary foot. In the original account of its anatomy it was thereupon suggested that this muscular development of the mantle must be "one of the principal instruments in the work of excavation."¹ But viewing its attachment to the moveable valve, and the strength of the adductor muscles, it was also supposed that that valve might be applied not only to effect the forcible expulsion of the fluid from the pallial cavity, but probably to assist in the excavation of the abode." Mr Hancock² has recalled attention to the excavating agency of soft and muscular masses in other boring Bivalves analogous to that in *Clavagella*; such as *e.g.*, the thickened portion of the mantle in *Saxicava* and *Gastrochaena*, and the foot in *Pholas* and *Teredo*.

If siliceous particles be actually secreted in the superficies of any of the burrowing discs, they must add to their efficiency; and it is certain that the perpetual renewal of a softer surface will render it capable of wearing away a harder one, subject to the friction of such softer surface, and not, like it, susceptible of being renewed.

The admission of the wearing and boring power of muscular discs need not, however, involve the rejection of the allied action of shelly valves and ciliary currents. The diversity of the organization of the boring Mollusks plainly speaks against any one single and uniform boring agent in all.

The action of the foot and thickened border of the pedial aperture may be inferior to that of the valves in *Teredo*, as it certainly is in *Pholas*. A valued correspondent, Mr Robertson of Brighton, informs the writer—"Between thirty and forty *Pholades* have been at work in lumps of chalk, in a finger-glass, and a pan of sea-water, at my window for the last three months. The *Pholas dactylus* makes its hole by grating the chalk with its rasp-like valves, licking it up, when pulverized, with its foot, forcing it through its principal siphon, and squirting it out in oblong nodules. They turn from side to side, never going more than half round in their hole, and cease to work as soon as the hole is deep enough to shelter them." The *Pholades* attain their largest size in soft yielding stone; whilst in hard, and especially gritty rocks, they are dwarfed in size, and the rough surface of their shell is worn away. M. Caillaud has shown that the "valves are quite equal to the work of boring in limestone, by imitating the natural conditions as nearly as possible, and making such a hole with them."³

The foot of the *Pholas* affords the requisite external fixed point or fulcrum on which the power of rotation by internal muscular motion depends. In *Lithodomus* (the *Dactylus* or date-shell of the conchologists prior to Linnæus), in *Saxicava* and *Ungulina*, the foot is too feeble to serve as such a fulcrum, and the valves are smooth, and retain the periostracum; yet they bore into the hardest marble, and still harder shells; their holes, like that of *Clavagella*, are not cylindrical, and are doubtless formed, as in that genus, by the agency of the thickened muscular borders of the pedial aperture.

Teredo navalis bores in the direction of the grain, unless it meets another *Teredo*, or a knot in the timber; they are probably warned by their organ of hearing of such contiguity. The rasp dust is introduced by the foot into the pallial cavity, and is swallowed. The long intestine of the ship-worm is usually laden with this debris.

GENERATION AND DEVELOPMENT OF THE LAMELLI-BRANCHIATA.

All Bivalves are richly prolific. Countless myriads of sperm-cells are developed in the one sex; and the ovium

swells with germ-cells as countless in the other sex. When the sperm-cells in the male oyster, *e.g.*, have been developed into moving filaments, and are excluded as such, these are drawn into the pallial cavity of a contiguous female along with the respiratory currents of sea-water; and at this season the oviducts are seen to contain a milky fluid abounding with spermatic filaments. By virtue of the action of the vibratile cilia of the mantle and gills, impregnation is effected in the Bivalves of distinct sex; even when, like the oyster, both male and female are cemented to the rock; just as the pollen of the rooted male of the dioecious palm is wafted by currents of air to the moist stigma of the equally fixed and rooted female tree.

In the *Naiada*, as has been remarked, the impregnated ova are hatched in the cavity of the outer gill, as in a marsupial pouch. The germ-mass, in the progress of development, becomes covered by a ciliated epithelium. In the group of four eggs of the *Unio litoralis* (fig. 26), the little arrow indicates the course of the rotation of such advanced germ-mass in the fluid albumen which divides it from the chorion, or transparent flexible "egg-shell."

Fig. 26.
Fry of *Unio litoralis*.

This singular phenomenon was discovered by Leeuwenhoek in 1695. When the rotation of the embryo is most active, seven or eight revolutions may be observed in one minute. Two parallel fissures next divide the germ-mass, at the bottom of which the visceral mass first appears. As it protrudes, the diverging moieties of the germ-mass assume the character of the "mantle-lobes," or rather of a body potentially including the gills and shell with those lobes, those three parts being subsequently differentiated. The gills make their appearance as ciliated, wavy folds (fig. 27, b) from the inner surface of the mantle, near the angle between the pallial lobes and visceral mass. The cleavage of the primitive germ-mass appears at first like an attempt at spontaneous fission. Each embryonal moiety has its own mouth, stomach, and heart; and it is by the subsequent approximation and fusion of the two ventricles that the common rectum of the two originally distinct intestines is intercepted, so as to seem to pass through the heart. The rest of the alimentary canal blends with its fellow as the visceral mass grows up from the bottom of the cleft, which growth is due chiefly to the progressive increase of the testis or ovarium; and thus two sexless individuals combine to form one with sexual organs.

By the phenomena observed in the progressive building up of the embryo Lamelli-branch, we learn the cause or chief condition of that most singular anatomical fact, which previously was a mere empirical one, without intelligible explanation—viz., the passage of the rectum through the centre of the ventricle of the heart. Calcification commences at the outer surface of the lobes, and the first layer of the future shell forms a small triangular valve on each side. The development of the adductor muscle, single at the beginning and near the hinge, is indicated by feeble attempts at opening and closing the valves. The albumen during this development is absorbed and assimilated, and the embryo now distends the chorion. The large detached ovum in fig. 26 exhibits the embryo *Unio*, or fresh-water mussel, ripe for exclusion. It escapes from the chorion before it quits the branchial marsupium. Filamentary processes, twisted together, resembling a "byssus," project from the visceral mass. The borders of the valves are broken and armed with spines. The young

² Annals and Magazine of Natural History, 1848.

³ Woodward's Manual, p. 327.

Encephala. of all the *Naiades* anchor themselves, soon after quitting the parent, by this byssus, which is temporary; the full-grown and strong-shelled animals do not need it.

The embryos of many Bivalves have locomotive structures equally temporary. Those of *Crenella marmorata*, e.g. (fig. 27), show a broad disc fringed with long cilia *d*, and provided with a slender tentacle *f*, which seems to be an organ of exploration. As the pallial lobes and valves *v*, *v* grow, the swimming disc decreases, and gives place to the labial palpi and the foot. The youthful excursion being ended, a byssus is finally formed to anchor the maturing *Crenella* to its final place of settlement.

In fig. 28, the embryo of the mussel (*Mytilus edulis*, after Lovén), *e* marks the eye-speck which disappears

with the locomotive power; *e* is the acoustic vesicle; *lt* the labial tentacles; *ss* the stomach; *l* the liver; *b* the branchiæ; *h* the heart; *v* the vent; *a, a* the anterior and posterior adductors; *f* the foot.

MOLLUSCA ENCEPHALA.

About three-fourths of the *Mollusca* are "Encephalous," or have a distinct head, commonly with eyes and tentacles, and the mouth has a peculiar and complex preparatory organ of digestion.

The mantle, properly so called, is to be distinguished, as in the foregoing group, from the ordinary external tegument. It is the free fold or folds of the skin, produced usually from the dorsal surface, and is in functional relation with the breathing organ and the shell.

Any part of the skin of a Mollusk, even that covering the foot, as in *Lithedaphus*, may produce a calcareous plate, but it is, as a rule, the function of the mantle-lobe or lobes.

In the following descriptions of the Cephalous Mollusks, the part answering to that marked *aa* (in fig. 70), is called the anterior or fore-part; the opposite end is the posterior or back part. *B* denotes the ventral or lower surface, *C* the dorsal or upper surface of the body.

The parts called "horns" or tentacles, but which are organs of sense or of exploration, not of prehension or

offence, are in two pairs in many *Encephala*. The anterior pair, in which the olfactory sense may well reside, are usually also less dorsal in position than the posterior pair, with which the eyes are frequently connected.

The acoustic sacs are connected with the suboesophageal or pedal ganglia in most *Encephala*, but receive their nerves from the superoesophageal ganglia, in some species. In Encephalous Mollusks, as in fishes, the auditory concretions present themselves in one of two forms,—viz., as solitary otoliths or as granular otocones.

A very characteristic feature of the organization of the head in the Cephalous Mollusks is the complex dentigerous rasping or boring organ (figs. 29 and 96), called by some the "buccal mass," by others the "proboscis," and by others the "tongue." As it coexists with lateral horny

Fig. 29.
Glottidium (Nudibranchiate Mollusk).

jaws in some species, e.g., *Eolis* (fig. 29, *c*) and *Tethys*, and with vertical ones in others (*Cephalopods*, fig. 96), it seems most homologous with the protractile dentigerous tongue in Myxinoid and other fishes; but as precise homology cannot be predicated of the parts of animals developed on plans so diverse as the vertebrate and molluscan, it seems best to designate the apparatus in question by an arbitrary "molluscan" term, e.g., "glottidium."¹

This is formed by a basis (chondrium)² *d*, of usually cartilaginous consistency, composed sometimes of a single piece, as in the *Aplysia*, but more usually of a pair, or with accessory pieces; the limpet, e.g., has four "chondria." The chondrium is convex towards the upper and fore part of the mouth. It is more or less enveloped by muscular fibres; some (*glottidiales*), *e*, passing to the cephalic parietes for the protrusion and retraction of the entire glottidium; others (*radulares*), *f*, inserted into the "radula"³ *g*. The rasping part, so called, consists usually of an elastic membrane stretched over the convexity of the chondrium, and supporting a spinigerous membrane or "tooth-strap."

The "glottidiales" are protrusors and retractors. The protrusor muscles are usually two on each side, which pass forwards to be attached to the walls of the head or to a more advanced part of the mouth-channel. The "radulares" are usually in two sets, radiating and transverse. The radiating series, *f, f* are the thickest, and often present a reddish colour. They arise from the back and under part of the "chondrium," and diverge as they ascend to be inserted into the extremities and sides of the radula. The thinner transverse fibres, when present, combine with the more constant diverging ones, in moving the radula to-and-fro upon the chondrium alternately raising and depressing the denticles by the same rasping or sawing movement.

¹ Gr. γλῶττα, "tongue."

² χονδρίον, deriv. from χονδρος, "gristle."

³ Lat. for "rasp."

Encephala. This mechanism seems to have been much misunderstood. Mr Huxley, for example, states that "the resulting action is precisely that of a circular saw;"¹ but the distinctive action of the circular saw is to rotate in one direction: the "radula" of the Mollusk acts like a common saw or rasp, by alternate movements to and fro.

The lining membrane of the mouth commonly protrudes in folds near the glottidium, as at *h* (fig. 29) in *Eolis* and in *Onychoteuthis* (fig. 96). The epithelial covering of the inner side of these folds in the Cephalopod is beset with series of short retractile horny teeth. Another complexity in the higher Mollusks, and one which adds to the lingual analogy of the glottidium, is the development in advance of the "radula" of one or more soft papillose and apparently gustatory lobes *z*. These caruncles have special retractor muscles; and the anterior "radulares" derive in Cephalopods an origin from the base of the lower jaw.

In fig. 29 of the mouth and glottidium of a Nudibranchiate Mollusk, *a* is the outer lip; *b* the inner lip; *a* is the margin of the vertical jaw; *c* the fleshy mass supporting the jaws; *c* the constricting muscle of the mouth; *d* the "chondrium;" *e* the "glottidiales" muscles; *f* the "radulares;" *g* "the tongue-strap;" *h* the buccal fold; *l* the oesophagus.

The teeth are set upon either a broad or a narrow band; in the former a median series of teeth or "rachis" is flanked by two lateral series or "pleuræ," as in the Gastropod called *Bezoardica glauca* (fig. 30). In some the "rachidian" teeth, in others the "pleural" teeth, are absent; and the number of longitudinal rows of these divisions may also differ in different genera. According to these differences, which, from their constancy, are valuable as generic characters, they may be indicated by the terms uniserial, biserial, triserial, septiserial, or multiserial, as, *e.g.*, in *Melania* the rachis is uniserial, the pleuræ triserial. Whether the "chondria" or lingual cartilages consist of a single piece thinner in the middle line, or of two or four pieces united by ligament and muscle, the dental sac is lodged at the back, and the dental band is stretched over the upper and fore part of the chondrium. Herr Trotschel² has devoted twenty years to the study of the dentition of the Mollusks, which he regards as important as that of any vertebrate class of animals.

The peculiarities of the circulation in the Encephalous Mollusks, which have given rise to the erroneous ideas of the absence of proper walls to the circulating sinuses, and the conditions originally attributed to that system in certain *Encephala*, under the term "phlebenterism," make it desirable to premise a few observations on the true state of the diffused venous system in other classes of Invertebrata.

John Hunter first observed, that "the veins of the insect would appear to be simply the cellular membrane; but they are regularly formed canals, although not so distinctly cylindrical canals as in the quadruped, &c., nor branching with that regularity. They would appear to be, or to fill up, the interstices of the flakes of fat, air-cells, muscles, &c., and therefore might be called, in some measure, the cellular membrane of the parts." (Hunterian MS. Catalogue, printed in the *Physiological Catalogue*, tom. ii., p. 31 (1834).)

Baron Cuvier, as is well known, entertained, with regard to the vascular system of insects, ideas closely akin to those

which some of his pupils have more recently expressed by *Encephala*, the term "phlebenterism;" for Cuvier supposed that the whole of the blood of insects stagnated in the lacunæ or cellular interspaces of the several organs: he was consequently led to deny that insects possessed a true circulation, or that the dorsal tube ("heart," extending through the whole length of the animal," Hunter, *op. cit.*, 1793, p. 137) acted as a heart. The more truthful views of Hunter, based on the analogy of the already commencing irregularity and extent of the venous sinuses in the lobster and snail, have been amply confirmed by the researches of Professor Carus, on the "Circulation of the Blood in the larvæ of Ephemerides and Libellulæ."³

With regard to the Crustacea, Hunter, who left preparations, and a beautiful series of drawings, illustrative of the circulating system in the lobster (*Astacus marinus*), thus describes the latter:—

"The veins in this class of animals, as in the winged insect, &c., are principally in the form of large irregular cells, as if the cellular or investing membrane of the animal contained the venal blood; and, when injected, we find the injection principally in large masses." He then, referring to his figures, describes the different sinuses, as "*a*, a large mass of vein lying on the stomach; *b*, another mass similar to the above, lying principally on the heart, which might almost be considered an auricle, as from it are openings into the ventricle." (Hunterian MSS., in *Physiological Catalogue of the Museum of the Royal College of Surgeons*, vol. ii., 1834, p. 138.)

The conditions of the vascular system in insects, crustaceans, and the snail, enunciated in brief but clear general terms in the work *On the Blood*, 4to, 1793, and exemplified by preparations, drawings, and manuscript descriptions left by Hunter in his museum, at his demise in the same year, appear to have passed unappreciated abroad, until the successive discoveries of analogous structures in other invertebrata, or the re-discovery of the same structures in the same species which Hunter had dissected, had been made.

Baron Cuvier appears to have been the first to recal the attention of comparative anatomists to this diffused and expanded condition of the venous system in his dissection of the *Aplysia*; but he mistook the expanded sinuses which fill the abdominal cavity, like those in the snail and slug, for that cavity itself. Describing the *venæ cavae*, which perform the office of the branchial arteries, he writes:—"Leurs parois se trouvent formées de rubans musculaires transverses et obliques, qui se croisent en toutes sortes de sens, mais qui laissent entre eux des ouvertures sensible à l'œil, et encore plus à toutes les espèces d'injections, et qui établissent une communication libre entre ces vaisseaux et la cavité de l'abdomen; de manière que les fluides contenues dans celui-ci pénètrent aisément dans ceux-là, et réciproquement."—"Il résulte toujours que les fluides épanchés dans la cavité abdominale peuvent se mêler directement dans la masse du sang et être portés aux branchées et que les veines font l'office des vaisseaux absorbants. Cette vaste communication est sans doute un première acheminement à celle bien plus vaste encore que la nature a établie dans les insectes, où il n'y a pas mêmes de vaisseaux particuliers pour le fluide nourricier."⁴

Jurine, in 1806, observing living specimens of a minute crustacean (*Argulus foliaceus*) which were asphyxiated by a few drops of alcohol added to the water they were in, traced the course of the circulation, which he describes, remarking:—"J'ai évité d'employer le mot *vaisseau* pour désigner les conduits dans lesquels le sang circule, et que j'ai remplacé ce mot, tantôt par celui de *colonne*, tantôt par

Fig. 30.

³ *Das Gebiss der Schnecken*, &c., 4to, 1856.

Encephala. celui de *rameau*. Les raisons qui m'ont engagé à le faire reposer sur la manière dont s'opère cette circulation. En effet, le sang chassé dans la partie antérieure du teste paraît s'y répandre et s'y disséminer de ces parties, plutôt que d'être contenus dans des vaisseaux particulières. Je ferai cependant observer qu'il existe dans ce liquide quatre espèces de courans qui ferment les quatre rameaux dont j'ai parlé plus haut, et que, dans les ailes comme dans la queue, la circulation ne se fait pas d'une manière aussi diffuse que dans la partie antérieure du teste, le liquide globuleux paroissant y être renfermé dans une espèce de large canal pratiqué dans le parenchyme de ces parties."¹

It was probably owing to the misinterpretation of the remarkable facts which Cuvier had observed, that Meckel, notwithstanding the analogous structures, in the meanwhile pointed out by Jurine in the *Argulus*, and by Gaspard² in the *Helix pomatia*, was led to deny the existence of the apertures of communication observed by Cuvier in the large muscular *venæ cavæ* of the *Aplysia*. In 1832, however, the writer of the present article detected a structure in the venous system in the *Nautilus Pompilius* closely analogous to that which Cuvier had pointed out in the *Aplysia*; but, having traced the continuity of the proper lining tunic of the great muscular *vena cava*, through the apertures in that coat, with a similar membrane lining the abdominal cavity, he was led to describe the tunic of the abdominal sinus as the peritoneum. "There are several small intervals left between the muscular fibres and corresponding round apertures in the membrane of the vein and in the peritoneum, so that the latter membrane is continuous with the lining membrane of the vein."³ And, after referring to the analogous structure in the *Aplysia*, the author adds, that this correspondence leads to the "suspicion that it may be more generally found on a further and more diligent investigation of the venous system in this remarkable class of animals."

Ten years later, M. Pouchet,⁴ professor of Zoology at Rouen, demonstrated in *Limax*, a structure answerable to that which M. Gaspard had described in *Helix*, viz., that the blood passed from the arterial capillaries into the visceral cavity, whence it was received by particular orifices into the veins that carried it directly to the pulmonary chamber, ramifying there like a *vena portæ* before returning to the heart.

In 1834, the same year in which were published the figures and descriptions by Hunter of the circulating system in the lobster, M. Milne Edwards recorded his examination of the same system in the same species, in the *Histoire Naturelle des Crustacés*, vol. i., p. 101. He there describes the expanded venous sinuses, as "plutôt des lacunes situées entre les divers organes que des canaux à parois bien formées." (Op. cit., p. 102.) the term "lacunes" is also adopted for that of "venous sinuses" by the editor of the posthumous edition of the *Leçons d'Anatomie Comparée* of Cuvier, t. vi., 1839, pp. 504, 505.

In 1843 M. Quatrefages⁵ believed that he had discovered a Mollusk, his *Eolidina paradoxa*, in which the organs of circulation were reduced to a univentricular heart and a system of arteries. "Le système veineux," he writes, "manque entièrement. Il est en quelque sorte remplacé par des lacunes du tissu aréolaire." In the same Nudibranchiate Mollusk the ramifications of the alimentary canal are also described as penetrating the branchiæ, "where the chyle was directly submitted to the atmospheric influence exercised by the surrounding water." To this supposed condition of the digestive, circulating, and respiratory systems, he

gave the name, "Phlebenterism," and proposed thereon some corresponding changes in the classification of the Mollusca. Pteropoda.

In the *Report* on this and other memoirs of M. Quatrefages on the Nudibranchiate Mollusks, by M. Milne Edwards, that distinguished professor adopts the mode of interpreting the modification of the venous system, and applies it to the Crustacea. "Il existe (dans le genre *Eolidine*) un cœur et des artères bien constitués, mais pas des veines proprement dites, et le sang ne revient des divers parties du corps que par un système des lacunes irrégulières, disposition tout-à-fait analogue à celle dont les Crustacées nous avaient déjà fourni un exemple. Enfin dans d'autres espèces, que M. Quatrefages a découverte sur les côtes de la Bretagne, le cœur et les artères disparaissent à leur tour; de sorte que la circulation devient des plus incomplètes et ressemblent à celle qu'on aperçoit chez les Bryozoaires." Subsequent researches by Messrs Embledon and Hancock demonstrated, however, the existence in the genera *Eolis* and *Actœonia*, of both heart and arteries; and the same careful anatomists confirm the observations of M. Souleyet,⁶ that the veins were not wanting in the Nudibranchs, but had only undergone that modification of form to which the term sinuses is more properly given. Not any of these authors have, however, published exact and recognisable representations of the relations of the attenuated *tunica propria* of the veins, to the interspaces or laminae which that tunic lines in forming the large and irregular sinuses in which the blood is diffused.

In several of the writer's monographs, and especially in plate iii., fig. 1, of that on the organization of the *Brachiopoda*,⁷ he has adduced evidence in proof that the diffused and supposed merely lacunar venous system is continuous, i.e., forms a part, by continuity of tissue, with the rest of the circulating system. Thus all ulterior researches rightly interpreted, since the time of Hunter, have served to confirm and establish the accuracy of that great anatomist's appreciation and explanation of the facts he discovered in insects and crustaceans, and to extend our knowledge of the same modification of the venous system as it exists in the series of the Molluscos animals.

CLASS IV.—PTEROPODA.⁸

Encephalous Mollusks with wing-like fins from the sides of the head or neck.

The *Pteropoda* are so called on account of the resemblance of their principal organs of motion to a pair of wings, both as to form and in their mode of action on the surrounding medium. These expanded fins are not, however, the homologues of the part called the "foot" in Gastropods.

The *Pteropoda* are small marine floating Cephalous Mollusks, many of them of minute size. The greatest extremes in variety of form are presented in this order,—some species of *Hyalæa* (fig. 31) and *Euribia* (fig. 40) being globular; others, as certain *Cleodoreæ* (fig. 34), being very long and slender. The body is divided into a "somatal" and "visceral" part.

In some—e.g., *Hyalæa* (fig. 31), *Spirialis* (fig. 42), and *Cymbulia* (fig. 39)—the head is not distinct from the muscular part of the "soma;" in others—e.g., *Clio* (fig. 45), *Pneumodermos* (fig. 46)—it is defined therefrom by a constriction or neck. In the seemingly headless group (*Thecosomata*) the fins are confluent by their bases at the mid-line of the dorsal aspect; in those with distinct heads (*Gymnosomata*) the fins spring separately from the sides of the neck.

⁸ Gr. "wing-footed."

Pteropoda. As in most other natural groups of Cephalous Mollusks, some Pteropods are naked, others provided with shells; the former have the best developed and most distinct heads. The mantle presents corresponding modifications, or rather the part of the skin, properly so called, exists only in the testaceous Pteropods. In them the pallial fold is reflected forwards over the visceral mass, leaving a wide anterior opening for the access of water to the gills, which the mantle thus conceals; it sends out processes conformable to those of the shell. Its surface is ciliated. In the naked Pteropods the integument is confined to the surface of the animal, and is perforated only by the alimentary, excretory, and genital orifices. It is thick, and of a firm—sometimes almost cartilaginous (*Euribia*)—texture.

The shell presents as extreme varieties of form as does the body, but is always characterized by the delicacy and transparency of its texture in these little floating Mollusks. It deviates least from the ordinary form of the spiral univalve in the *Pteropod*, called on that account *Spirialis*. In this genus (fig. 42) the shell is discoid, with the last whirl much expanded, and umbilicate; the rest are disposed in from three to five whirls, projecting more or less from the last, with the mouth often angular; and in some (*Sp. ventricosa*) subcanaliculate the shell is sinistral. Some of the species (e.g., *Sp. clathrata*) are provided with an operculum (fig. 43). In *Limacina* the turns of the shell are reduced to one whirl and a half. In *Hyalæa*, fig. 32, the shell resembles a bivalve in which the two valves have been cemented together along the hinge, leaving a narrow fissure in front and at the sides. In *Cleodora*, fig. 34, the shell is narrowed and lengthened out, the two plates being united together along the sides, so as to leave only an anterior aperture. In *Cymbulia*, fig. 39, the shell is internal, symmetrical, shaped like a boat or slipper, and of a gelatinous-cartilaginous texture. The cephalic ganglions (fig. 35, *b*, nervous system of *Cleodora*) are united by a commissural band *a*, passing above the œsophagus. The pedial ganglia *c*, and the "branchial" or splanchnic *d*, form a mass which is below the œsophagus.

No Pteropod possesses very distinct or well-developed eyes; but the acoustic, or little sac with calcareous crystals attached to the subœsophageal ganglions, exists in all, and was first discovered in these delicate subtransparent floating Mollusks.¹

The testaceous Pteropods have two tentacles; the naked ones have four. In these the vent is on the right side of the body, whilst in most of the testaceous Pteropods it is on the left side, the shell where spiral being sinistral. The heart consists of an auricle and ventricle, its position varying with that of the gills, which offer extreme modifications in this circumscribed group.

The organs of the male and female sex are combined in the same individual. The most essential part of the complex generative organs of hermaphrodite Cephalous Mollusks, which had been alternately described as testis and ovarium by different authors, before accurate microscopic observation had proved that both organs were combined in the same body, will be called in this article the "ovispermial" gland or body. The generative orifices are on the right side, save in *Cymbulia*, where that of the penis is median; the organ so called is for excitation, being imperforate, and is remote from the sperm-outlet

ORDER I.—THECOSOMATA BL

With an external shell; head indistinct

Genus.—HYALÆA,² Lamarck.

Sp. Hyalæa tridentata (figs. 31, 32).—The shell of *Hyalæa* Pteropoda consists of two plates, which, like the valves of a Brachio-

Fig. 31.
Hyalæa tridentata.

pod, are "dorsal," *f*; and "ventral," *g*, in relative position. It bears, indeed, such a resemblance to a Bivalve, that Forskæl,³ its discoverer, referred it to the genus *Anomia*, as *An. tridentata*. To Cuvier⁴ belongs the merit of having determined, by anatomical investigation, the pteropodal affinities of the beautiful little Mollusk, for which Lamarck, after Lamar-tinière's remarks on the affinity of the shell to that of Brown's *Clio*, proposed the name of *Hyalæa*.

The animal consists of a "somatal" (fig. 33, *C*, *d*) and "visceral" (*g*, *h*) division. The former is a broad, depressed muscular part, from which the head is not distinct, expanding on each side into a fin *C*, with a trilobed margin, the fins being united by a middle plate or lobe *d* (fig. 33), continued from their hinder border across the ventral aspect of the body.⁵ The head is indicated by two small clavate tentacles (fig. 33, *b*), and by the mouth *a*, which opens on the ventral aspect, and is provided with two labial appendages (fig. 32, *f*). The visceral division is lodged in the shell; the mantle opens in front, and sends off from its sides variously-shaped extensible appendages (figs. 31 and 33, *e*). The vent (fig. 33, *o*) is on the left side of the body, near the anterior border of the mantle and the left extremity of the gill. The vulva *y* is on the right, behind the base of the right fin; the male outlet is upon the right cephalic tentacle *b*. The gill (fig. 33, *z*) is horse-shoe-shaped, and circumscribes the visceral mass behind and at the sides, being quite concealed by the mantle. The shell (fig. 32) is vitreous, transparent, and fragile; symmetrical; more or less globose, chiefly by the convexity of the ventral valve *g*; it is tridentate behind, with the angles or teeth *h* (figs. 31 and 32) more or less produced, according to the species, with a fissure-like opening *i*, anteriorly and laterally, not adapted for closure by an operculum. A single retractor muscle (fig. 33, *k*) arising from the median point or apex of the shell, passes forward along the dorsal aspect, expanding, and then bifurcating to spread abroad and interlace with the muscles of the fins. By the action of this retractor the whole "soma" can be retracted within the shell; the lateral prolongations of the mantle have their own contractile fibres for the same purpose.

For a full description of the nervous system of *Hyalæa* the reader is referred to the *Voyage de la Bonite*, Partie Zoologique, tom ii., 8vo, p. 131, and *Atlas*, fol., pl. 9, figs. 20–24, whence the figures referred to are taken.

The labial boundaries of the triangular mouth are prolonged, and subside in the grooves between the fins and middle lobes of the soma. The glottidium has three diverging series of minute recurved teeth.

⁴ Gr. for "glassy."

⁵ *Annales du Muséum*, tom. iv. (1804), pp. 223–234.

Pteropoda. The cesophagus, after traversing the nervous ring and entering the visceral cavity, expands into an ingluvial pouch, lined by an epithelium thickened into four longitudinal horny plates with sharp angles; the stomach, continued from this part, rapidly contracts into an intestine (fig. 33, *o*), which, describing a convolution round the liver *p*, is reflected forward and to the left, to terminate, as above described, at *o*.

The skin of the *Hyalæa* is produced and reflected from behind forwards, so as to form a true mantle, which circumscribes beneath the viscera a branchial cavity opening anteriorly. The branchial plates are attached to the bottom of this cavity, and are disposed, as Cuvier well described, in a crescentic curve, almost circumscribing the viscera. Within the horns of the crescent are two supplementary series of gill-plates, parallel with those terminal parts of the main series, and more dorsal in position. The pericardium lies behind the left supplementary gill; the anus opens in front of it. The gill-plates are like those of the limpet, but are more complex in structure. The urinary sac *q* surrounds part of the auricle *r*, the pyriform ventricle *s* sends off a short aorta, which divides into two main branches. The genital or ovispermal gland *u* is transversely ridged or folded; its duct enters the side of a second larger canal, with glandular walls, one end of which is prolonged into a convoluted blind tube *w*, the other terminates in a kind of matrix *v*, consisting chiefly of compacted convolutions of a tube. The duct or canal of the matrix (vagina *x*) passes forward and to the right, to terminate behind the right fin.

The exciting organ is a muscular tube *b*, whose folds form a prominence to which the upper border of the somatal integument is attached; the tube opens externally in front and to the right of the mouth; its internal dilated end appears to terminate as a closed cavity, connected only with a retractor muscle. It is thus insulated, like the palp of the male spider and the intromittent organ in some Cephalopods, from the remaining and more essential part of the male apparatus.

The *Hyalæa* inhabit the warmer temperate and tropical zones, and have been taken in the Atlantic, Indian, Pacific, and Mediterranean seas. They swim with moderate speed by the action of their fins, but always with the back downwards, which is indicated by the deeper colour of the more exposed convex ventral valve. More than twenty species

selected for the special illustration of the genus. The beautiful translucent shell of this species, about 9 lines in length, is of a reddish-yellow, shading off to rose colour, but pale on the dorsal plate. The ventral valve is marked anteriorly by fine transverse striæ. The dorsal valve has five convex aorta, which diverge forwards.

Genus CLEODORA, Péron, Lesueur. A beautiful transition from *Hyalæa* to *Cleodora* is made by the *Cleodora lanceolata*, Lesueur, in which the anterior borders of the shell are so produced as to make its fissured opening in part lateral as well as anterior; the productions of its apex and sides also resemble those of *Hyalæa tricuspidata*. Other *Cleodora* gain in length and lose in breadth, until the opening of the shell is wholly anterior, and its cavity prolonged into the tubular or serpuliform shape presented by the *Cleodora aciculata* (fig. 34).

The mantle sends out no lateral processes or enveloping folds in such *Cleodora*. The fins are simply notched or bilobed, and are more distinct from the median fold *d*. The mantle forms a pouch for the branchiæ like that of the *Hyalæa*; its muscular border follows closely the progressive modifications of the shell aperture, and becomes simply circular anteriorly, as at *e* in the species figured; it is beset with tufts of vibratile cilia, as in *Hyalæa*. Save in the modifications of proportion, chiefly of length, conform-

Fig. 34.
Cleodora aciculata.

ably to the altered form of the body, the digestive organs closely resemble those of *Hyalæa*. In fig. 35, *a* is the buccal mass, *l* the gullet, *n* the stomach, *p* the liver, and *o* the intestine, which terminates further from the free border of the mantle than in *Hyalæa* at *o*. The gill forms half of a longer and narrower ellipse than in *Hyalæa*; the heart has a similar relative position, and consists of the usual auricle and ventricle, but the urinary cavity is a more distinct pyriform sac than in *Hyalæa*. The ovispermal gland (fig. 35, *u*) is sub-bilobed and transversely plicated. The oviduct is continued directly into the glandular tube *v*, which is not prolonged into a cæcal appendage, but contracts as it terminates in the matrix *w*. The genital outlet *y* is behind the right fin; the exciting organ is disconnected with the essential part of generation, and is more in advance. The retractor muscle *h* closely resembles that of *Hyalæa* in its origin and insertions.

Fig. 33.
Hyalæa tridentata (magn.)

have been defined,¹ of which the *Hyalæa tridentata* is here Difficult as it is to differentiate in any very essential degree

¹ Many of which are beautifully figured in the *Voyage de la Bonite*, plates 4, 5, and 6.

Pteropoda. *Cleodora* from *Hyalæa*, it is still more so to discriminate from *Cleodora* the more slender conical species which have been removed from that genus under the names *Styliola* and *Creseis*.

In the *Cleodora cuspidata* and *Cleodora pyramidata* the shell is pyramidal, three-sided, striated transversely with the mid-costa, in the dorsal valve, so produced as to give it a keeled appearance. In *Cleodora virgula* and *Cleod. aci-*

Fig. 35.
Cleodora pyramidata.

culata the shell shows neither aortæ nor striæ, and is truncate anteriorly. The fins have a small lobe on their inner border.

The geographical distribution of the species of *Cleodora* agrees with that of *Hyalæa*.

Genus *CUVIERIA*,¹ Rang.—The Pteropods of the genus *Cuvieria* are closely allied to the *Cleodora*, and were ascribed to that genus by their discoverer M. Gaudichaud (as *Cleodora obtusa* and *Cleod. rosea*). The fins (fig. 36, c)

Fig. 36.
Cuvieria columnella.

have the same elongated form and terminal notch; but the intermediate lobe *d*, which some suppose to be homologous with the part *f*, fig. 67, in *Carinaria*,² presents also a notch at its middle part.

The *Cuvieria* are also more particularly distinguished by an appendage, which is attached to the under part of the neck by a pedicle, and divides into two lobes, one (fig. 36, e) elongated and pointed; the other, *f*, expanded, and with a thickened, wavy, or plicated border. From the lower part of the pedicle a fold of skin connects the terminal orifice of the vagina with the neck; and the bifid appendage is probably the homologue of the penis in Heteropods. The mantle does not develop lateral leaflets, as in *Hyalæa*.

The crescentic branchia (fig. 38) is placed deeper in the Pteropoda. mantle-bag than in *Cleodora*, and its horns are less symmetrical. The shell (fig. 37) has a septum *s*, which partitions off its hinder end; and its aperture *i* has a rounded, not a trenchant border. M. d'Orbigny affirms that the hind end *g* is originally pointed as in *Cleodora*, and that its usual truncation is due to accident.

In fig. 38, *i* is the branchia, *r* the auricle, *s* the ventricle, and *t* the pyriform urinary sac.

The *Cuvieria* range from the tropics to the latitude of Cape Horn. They are less common than the *Hyalæa* or *Cleodora*, but their mode of life is the same.

In the *Cuvieria columnella* (figs. 36 and 37), the shell is sub-cylindrical, elongated,

smooth, contracted, or truncate at the hind end *g*; depressed anteriorly, with an oblique aperture *i* with rounded borders, the dorsal longer than the ventral lip.

Three varieties of form of this shell have been noticed: in the first two the shell is moderately thick, firm, hyaline, sometimes of a feeble rose colour, and with fine longitudinal striæ; in the third variety the shell is thin, fragile, and quite transparent. The latter variety occurs in the Chinese and Pacific Oceans.

Genus *CYMBULIA*, Péron and Lesueur.—In this genus the cartilaginous shell is developed in the substance of the mantle, but is distinct. It is covered by so thin a layer of the mantle that this is often torn, and the animal loses its shell, which slips out; its substance contains chitine. It is transparent, skiff-shaped, symmetrical, pointed in front, truncate behind, with the aperture elongate and ventral.

The body of *Cymbulia Péronii* (fig. 39) is somewhat obscurely divided into a somatal and visceral part, the latter only being lodged in the shell. The fin-like expansions of the soma, *C, C*, are unusually large, expanding to beyond the hinder end of the body.

The mouth opens on the ventral surface of the body, at the anterior interspace between the fins. Above and in front of this orifice are two protentacles, in front of which, at the middle line, is the prepucce.

The visceral part is not inclosed by a pallial sac opening anteriorly, as in *Hyalæa*, but is covered by the mantle only dorsally; while on the ventral side it rests in a sac, formed by the detachment of the skin from the dorsal surface of the fins, and opening posteriorly. There are no proper or free "borders of the mantle;" that which circumscribes the orifice of the

Cymbulia Péronii.

¹ In honour of Cuvier, the founder of modern Malacology.

² "Fins united by a semicircular lobe, the equivalent of the posterior element of the foot." (Woodward's *Manual*, p. 204.)

Pteropoda. visceral cavity is a simple fold, which is reflected thence over the shell, which thus becomes "internal." The gills are two membrano-vascular plates on the sides of the visceral pouch.

Sp. *Cymbulia Péronii*, Lam.—This is the type species, and is met with in certain parts of the Mediterranean.

Two other species have been characterized as *Cymbulia punctata* and *Cymbulia Norfolkensis* by the naturalists of the "Astrolabe." These Pteropods swim, like the *Hyalea* and *Carinaria*, with the belly upwards. Mr Adams figures a *Cymbulia proboscidea*.

Genus *TIEDEMANNIA*, Delle Chiaje.—The Pteropods of this genus are *Cymbulia*, with the fins and foot-process confluent and forming an orbicular disc; the mouth is at the apex of a long proboscis; the tentacles are elongated and connate; the eye-tubercles minute. The shell is hyaline, gelatinous, slightly excavated; it appears to be soon or frequently shed.

Sp. *Tiedemannia Neapolitana*, V. Beneden (*Exercices Zootomiques*, p. 21, pl. 2).—In this species the proboscis is slender, and the fins have white and yellow spots at the margin.

Genus *EURIBIA*, Rang.—The genus *Euribia* is founded on a small and very rare Pteropod, of the shape and about the size of a pea. (See the figure opposite the left hand in fig. 41.) The chief part of the integument, although transparent, is of almost cartilaginous consistency, but anteriorly becomes suddenly thin and flexible, forming a fold, which borders on oblique fossa into which the "soma," or the fore part of the animal developing the fins and tentacles, and covered by a thin and extensible skin, can be retracted with all its appendages. The firm globular hind part of the integument, which thus acts as a shell, retains so much muscularity that it can draw one side of the anterior depression towards the other, and thus close the seeming aperture upon the contracted and retracted cephalic appendages, as in the enlarged figure opposite the right hand in fig. 41. Of these appendages the largest and most conspicuous are the fins (fig. 40, *c, c*), which are attached to the sides and under part of the head, meeting and partially blending at the latter aspect; but with a median pedial appendage *f* at the interspace. The fins curve backwards, and are dilated at their extremity.

Anterior and ventrad of the fins come off the long, transversely-striated, and pointed appendages (fig 40, *e, e*), and in front of these are the tentacles *l, l*. At the fore part of the right fin is the preputium; at the back part is the genital or vaginal orifice *y*. The vent *o* is to the right of the pedial appendage *f*. The mouth *a* is an elliptic aperture, with two labial palps or tentacles *d*. The "glottidium" has a biserial dental plate. The pair of cæcal salivary glands; the large stomach surrounded by the liver *p*; the reflected intestine *o*; and the androgynous generative organs *u, v, w*,—all accord with the pteropodal type. The retractor muscles of the soma are shown at *h, h* in fig. 35.

Fig. 40.
Euribia Gaudichaudii.

The *Euribia Gaudichaudii*, Eyd. and Soul., was captured by the accomplished naturalist after whom it is named in the Pacific Ocean, in 20. N. Lat. and 170. E. Long. He noticed in the living animal the vibratile action of tufts of cilia on the anterior border of the fins. These appendages were of a pale rosy tint; the visceral mass was partly brownish, partly of an orange-red.

The *Euribia Norfolkensis* (fig. 41), captured by MM. Quoy and Gaimard, off Norfolk Island, Australia, differs by the rugosities or minute tubercles which roughen the firm integument. Fig. 41 shows this part in its retracted and contracted state magnified; the figure to the left shows the aperture of the quasi-shell, a little widened, of the natural size.

Fig. 41.
Euribia Norfolkensis.

The small Pteropod which forms the genus *Psyche* of Rang appears to differ from *Euribia* only in the softer consistency of the integument. The name *Psyche*, moreover, is pre-appropriated by the Lepidopterists.

Euribia is in some measure intermediate between *Cuvieria* and *Pneumodermion*, and seems to indicate the transition from the naked to the shelled Pteropods.

Genus *SPIRALIS*, Eydoux and Souleyet.—Were the long and slender shell of *Cleodora* to be twisted spirally, and its anterior aperture widened and closed by an operculum, it would become transmuted into a *Spiralis* (fig. 42). The soma and its natatory expansions differ only by slight and unessential modifications of form from those of *Hyalea* and *Cleodora*. Thus the fins (fig. 42, *C, C*), are elongated, slightly expanded, and rounded at their termination. The intermediate lobe is sub-pedunculate, and bears the opercule *f* on its upper surface. There are two minute tentacles. The prepuce is at the front border of the head, a little to the right. The proper genital opening is behind the base of the right fin. The branchial sac is now dorsal in position, as in Gastropods, through the spiral twist of the body. About half a dozen species of *Spiralis* have been defined.

Fig. 42.
Spiralis Bulimoides (mag.)

The *Spiralis Bulimoides* (fig. 42) has an elongated sinistral shell of six whorls, with a sub-acute spire. The mouth is ovaloid, angular at the fore part, with the labrum sharp; the columella is slightly arched. The shell scarcely exceeds a line in length; it is smooth. The operculum (fig. 43, *f*) is chitinous, dextral, and paucispiral.

Fig. 43.
Spiralis (mag.)

In the *Spiralis clathrata* (fig. 44) the surface of the shell shows slightly elevated striæ, decussating so as to intercept lozenge-shaped areolæ. It has three sinistral whorls *g*, with a capacious ventricose last turn or chamber *f*. The minute Pteropods of this genus are abundant, and are widely diffused through the warm latitudes of the ocean.

Fig. 44.
Spiralis clathrata (mag.)

Genus *LIMACINA*,¹ Cuv.—This genus was proposed by Cuvier for the *Clio helicina* of Phipps,² and probably the generic name was given, as Van der Hoeven suggests, inad-

¹ Lat. for a "small slug."

² Voyage towards the North Pole, 4to, 1774.

Pteropoda. verterently for *Helicina*; the slug-like *Clio* being distinguished as the *Cl. Limacina* from the testaceous Pteropod now generally recognised as the *Limacina arctica*.

Limacina has a fragile, discoid, sinistrally spiral shell, deeply umbilicate on one side, and with the spire slightly projecting on the other. It differs from that of *Spirialis* in having no operculum.

Sp. *Limacina arctica*, Cuv.—This species exists in myriads in the arctic seas.

Sp. *Limacina antarctica*, Hooker.—The species in which the shell-whorls are transversely striated, with the fins notched on the hinder border, and with the post-pedial lobe emarginate, is equally abundant in the antarctic seas.

ORDER II.—GYMNOSOMATA, Blainville.

Without a shell; head distinct; fins attached to the sides of the neck.

Genus *CLIO*, Linn. and Müller.—The earliest form of Pteropod known to naturalists was a species of the genus to which the above name, originally applied by Brown to another form, and by Linnæus to all the Pteropods he knew, is now by common consent restricted. This species (*Clio borealis*, Gmel., fig. 45), the well-known whale's food, or "whale-bait" of the arctic voyagers, is remarkable for the high northern latitudes in which it exists, and for the myriads of its individuals that find subsistence in those icy seas. First indicated by Martens in his *Voyage to Spitzbergen* (1675), and afterwards described, as to external characters, by Pallas;¹ its true nature and affinities were made known anatomically by Cuvier.² Eschricht³ and Gegenbauer⁴ have ably completed that work, and a wonderful structure has been unfolded through their patience and skill. A study of the works cited below will well repay the earnest student of Molluscan organization.

In the genus *Clio* the body is oblong, acuminate, or appendiculate behind (*Clio longicaudatus*). The head (fig. 45, *a*) is defined by a constriction (*Clio borealis*), or by a neck (*Clio longicaudatus*); it is terminated by two cowls or hoods (*preputia*, Pallas), containing each three appendages (fig. 45, *a'*), and by a pair of retractile tentacles *b*. The fins *c* are more wing-shaped than in most Pteropods; their contracted bases are confluent across the ventral aspect of the "neck." In swimming, the *Clio* brings the ends of its fins almost in contact, first above, then below. The rudiment of the foot *d* is bifid. At the back of the neck are two black "ocelli." The preputium in front of the right fin gives exit to an unusually long bent excitatory organ *z*, when it is unfolded and everted. The vaginal orifice is behind the right fin. The vent *o* is still more posterior and nearer the ventral surface. The conical appendages of the head, when fully expanded, form a radiated crown;

Fig. 45.
Clio borealis.

they are of a red colour on the recent animal; which colour depends on the presence of numerous separate superficial points, about 3000 on each appendage. Each point, microscopically examined, is a sheath inclosing a central body composed of a stem terminated by a tuft of about twenty pedunculated discs. Eschricht, their discoverer, calls them suckers, and reckons up about 360,000 of them. Gegenbauer suggest that they may be pedunculated epithelial or pigmental cells or scales.

Sp. *Clio borealis*, Müller (fig. 45).—This species abounds in the neighbourhood of Greenland and Spitzbergen, and though scarcely an inch in length, constitutes, with its common associate, the still smaller Pteropod, *Limacina arctica*, the chief food of the great whalebone whale (*Balæna mysticetus*).

Sp. *Clio fusiformis*, Quoy and Gaimard (*Zoologie du Voyage de l'Uranie*, pl. 66, fig. 2); *Clio longicaudatus*, Eydoux and Souleyet (*Zoologie du Voyage de la Bonite*, pl. 14, figs. 19–21).

Genus *PNEUMODERMON*⁵ of Cuvier.—A naked Pteropod, about an inch in length, discovered by Péron in the Atlantic, and submitted to Cuvier's examination, was described by the great anatomist in the fourth volume of the *Annales du Muséum*, 1804, under the name of *Pneumodermon*, or "lung-skin," from the circumstance of the gills (fig. 46, *i'*)

Fig. 46.
Pneumodermon Péronii (mag.)

being distinctly developed from a part of the integument. Other species of this genus have since been discovered.

The head (fig. 46, *a*, and 47, *A*) projects anteriorly and distinct from the fins *c, c*; the mouth, when the mouth-mass *ad* is retracted, is a small terminal vertical slit, on each of which is a pit with a small pro-tentacle. The post-tentacles are still smaller, and are bifid. On the right side, in advance of the fin, is the preputial orifice; near the hind border of the fin is the vaginal orifice (fig. 47, *y*). Still further back, but still on the right side, is the vent (fig. 46, *o*). On the middle of the ventral surface of the anterior constricted part of the body is a heart-shaped disc (fig. 46, *d*), composed of two lateral plates united together and attached along the mid-line, but elsewhere free; from above the back part or base of the above disc a long triangular lobe (fig. 46, *f*) freely projects backwards. These appendages are homologous with the "fin-foot" and "tail" in Heteropods; like the foot-disc in which the *Pneumodermon* uses the discoid part (fig. 46, *d*), to attach itself to the sides of the glass in which it may be placed.⁶

² *Anatomische untersuchungen ueber die Clione Borealis*, Copenhagen, 1838.

³ *Untersuchungen ueber Pteropoden und Heteropoden*, Leipzig, 1855.

⁴ "Cet appendice est tout à fait analogue, par sa position et par sa forme, au pied des Mollusques Gastropodes—ses usages paraissent

être semblables à ceux du pied des Atlantes, des Firoles, &c., qui, comme on le sait, est transformé en ventouse dans une partie de son étendu." (*Zoologie de la Voyage de la Bonite*, tom. ii., p. 257.) The interesting homology above enunciated by MM. Eydoux and Souleyet, whose "beautiful plates, illustrative of the Zoology of the voyage of the Bonite," are referred to in another part of Mr Huxley's *Memoir* (p. 30), is adopted by that writer, who informs the Royal Society,—"It is very remarkable that Cuvier should not have recognised in the 'espèce de menton' and the 'deux petits lèvres' of *Pneumodermon*, the homologues of the foot of the Gasteropoda." ("On the Anatomy of certain Pteropoda," *Phil. Trans.*, 1853, p. 39.) The true discoverers of this homology, with more candour, point out the belief which Cuvier entertained of the existence of a fissure between the folds of the little foot, as the ground for his describing them as 'labial' folds. The anatomical illustrations of the Pteropoda here given are chiefly derived from MM. Eydoux and Souleyet.

⁵ *Annales du Muséum*, vol. i., p. 262, pl. 17.

⁶ Gr. for "lung-skin."

Pteropoda. The visceral division *op* (fig. 47) forms the seeming trunk of the animal; it is expanded, ovoid, and terminated behind by membranous plates which support the branchial filaments. There is also a vascular process *i* (fig. 46), where the integument is very thin, from the right side of the body a little in advance of the terminal branchial region *i'*, which process is most intimately related to the vascular and respiratory function.

The only part of the integument that can be properly regarded as "mantle" is the slightly projecting border *e* (fig. 46) from the four-radiate respiratory surface; elsewhere the skin is perforated only by the oral, excretory, and genital outlets.

On each side the buccal cavity is an invertible pouch (fig. 47, *a*), to the surface of which are attached numerous

Fig. 47.
Pneumodermon Péronii (mag.)

pedunculated suckers (fig. 47, *b*, and fig. 46, *l'*). The glottidium is notched before and behind, and each moiety supports four rows of recurved denticles. Beyond the glottidium are the orifices of two long accessory appendages, consisting of an outer sheath (fig. 47, *e*) having a muscular coat of longitudinal and circular fibres, and an inner tube lined by an uncinated membrane, capable of being everted and protruded (as at *d'*, fig. 46) when the hooks become external. The œsophagus has a sigmoid flexure by which it adapts itself to the varying conditions of the buccal appendages. The salivary cæcal glands (fig. 47, *f, f*) lie by its side. The stomach *m* is capacious, and seems to be a lining to the hepatic mass *p*; the intestine *o* is short, and is reflected forward to terminate on the right side (fig. 46, *o'*), some way in ad-

vance of the respiratory surface of the mantle. This surface is at the posterior part of the body (fig. 46, *ie*), which shows four curved membranous folds; the dorsal and ventral pair turn their convexities to each other, and are united by the shorter lateral folds, which circumscribe an irregular quadrangular space; the longer folds have a pinnate arrangement of branchial lamellæ *i*. On the right side of the body there is a process of the skin also supporting branchial lamellæ.

The heart, consisting of an auricle *r*, and a ventricle *s* (fig. 47), is situated at the back part of the visceral cavity, close to the part whence the last-mentioned branchial process projects. The aorta divides and sends one branch to the visceral mass, the other to the soma or rudimental foot and its appendages. The renal sac *q*, which Lovén deems homologous with the plicated auricles of *Terebratula*, is closely connected with the venous trunk entering the auricle in *Pneumodermon*. The male and female organs are combined as in other Pteropods. In fig. 47, *u* is the blended testis and ovarium, *u'* and *w* are the combined oviduct and sperm-duct, *v* is the uterus, *x* the vagina, and *y* the genital orifice.

Sp. *Pneumodermon Péronii*. Cuvier (fig. 46.— This species is of a violet-brown colour, deepening towards the head; the fins and branchial membranes are white; it is about an inch in length. The species is common in the Atlantic, in tropical latitudes. The individuals are aggregated in large groups; they swim swiftly, and in their natural position, with the ventral surface downwards, not reversed like the *Hyalea*. When at rest they can attach themselves pretty firmly to any floating body by their rudimental foot, or by their buccal suckers.

Professor Müller describes the larva of *Pneumodermon* as being girt by three bands of vibratile cilia, one round the fore part, another round the middle, and the third round the hind part of the body.

CLASS V.—GASTEROPODA.¹

The Encephalous Mollusca grouped together under the above name by Cuvier, include the most typical forms of the province; yet can hardly be regarded as so natural a class as either the *Brachiopoda*, *Lamellibranchiata*, or *Cephalopoda*. The muscular disc for creeping (fig. 48,

Fig. 48.
Cypræa tigris.

dd), which is developed from more or less of the ventral surface of the body, is the common external character by which the Gasteropods are associated together; and yet there are species (fig. 71, *e.g.*) in which the ventral foot

is as little developed, or recognisable as such, as its homologue is in *Pneumodermon* and some other *Pteropoda*.

The snails and slugs exemplify the ordinary mode and characteristic instrument of locomotion in the Gasteropodous

¹ Gr. for "belly-foot."

Gastero-
poda.

class, most of the members of which are unsymmetrical, with the visceral division of the body coiled spirally and protected by a shell; the breathing organs of the left side being, as a rule, atrophied. Most Gastropods are marine; some inhabit fresh waters; a few are terrestrial. The species offer corresponding conditions of the respiratory organs in relation to those media, with minor modifications, of which the systematic naturalist has availed himself in distributing the numerous and diversified members of the class into orders.

The air-breathing Gastropods (*Pulmonata*)¹ constitute a tolerably natural group: those that breathe water are much more diversified.

In certain small shell-less marine genera,—e.g., *Rhodope*, *Tergipes*, *Eolidina*,—no distinct respiratory organs have been detected: these form the order *Apneusta*.²

Some that breathe by gills have those organs exposed. The genera which support them on the back, such as *Glaucus*, *Scyllæa*, *Tritonia*, form the order *Nudibranchiata*;³ all the species are without shells in the mature state. Those genera which carry the gills at the lower part of the sides of the body, between the foot and mantle,—as, e.g., *Phyllidia*,—constitute the order *Inferobranchiata*; they are likewise naked when mature. The genera in which the gills have a similar position, but extend around the body, as in the limpet (*Patella*), and in *Chiton*, form the order *Cyclobranchiata*; they are protected by a conical shell composed of one or of many pieces.

In the rest of the water-breathers the branchia are concealed. Those genera,—as, e.g., *Aplysia* and *Bulla*,—which have the gills protected by a fold of the mantle containing a rudimental shell, or by a reflected portion of the foot, form the order *Tectibranchiata*.⁴

In all the foregoing orders of *Gasteropoda* the male and female organs of generation are combined in the same individual.

In the remainder of the class the sexes are distinct. A small order of marine Gastropods, in which the gills are packed in small compass, with the heart in a dorsal mantle-chamber or in a small symmetrical shell, is called *Nucleobranchiata*; and also, on account of their stunted foot, *Heteropoda*. Another small group of marine Gastropods, including *Fissurella* and *Halyotis*, which have their comb-like branchia protected by a wide shield-shaped shell, is called *Sentibranchiata*.⁵ A third small group in which similar branchiæ are protected with the entire body by a tubular shell, is called *Tubulibranchiata*. In the last, highest, and most extensive order, called *Pectinibranchiata*, from the comb-shaped gills, which have a special pallial cavity at the fore part of the back, and which, with the rest of the body, are protected by a spiral univalve shell, the males are provided with an intromittent organ. A few species of *Cymba*, *Liutorina*, *Paludina*, and *Helix* are ovo-viviparous; most Gastropods are oviparous. The young of the water-breathing Gastropods are excluded with a protecting operculated shell, which in the “naked” species is either shed or concealed by a fold of the mantle. They swim by means of a pair of ciliated fins attached to the sides of the head, and thus move far away from their inactive or sedentary parents. The larvæ, as they may now be called, of all the water-breathers are very much alike, and undergo metamorphoses in the course of attaining their adult, nudibranchiate, nucleobranchiate, or pectinibranchiate forms. The air-breathing Gastropods undergo no such metamorphosis: their shell commences by the deposition of crystals of carbonate of lime in the substance of their skin, above the visceral cavity, and it is persistent.

The soft parts of Gastropods are immediately invested by a soft inarticulated lubricous integument, forming in most a sub-circular fold (fig. 48, *i*) about the neck, behind which it is produced into a sac containing the circulating,

Gastero-
poda.

Fig. 49.
Dolium galea.

respiratory, and renal organs, which fold and sac are called the mantle. This is, then, continuous with the thin skin covering the rest of the visceral cavity, which is usually disposed in a spiral form, and adapted to the deep recesses of the shell. In the skin covering the “soma” (*i* to *d*, fig. 49) may be recognised an epidermal, a pigmental, and a dermal layer, the latter being of a musculo-cellular structure and highly contractile. The epiderm is ciliated over nearly the whole body in the aquatic Gastropods, but only in certain spots in the terrestrial species. The white stripe at the sides of the neck and foot of the wood-snail (*Helix memoralis*) are composed of short, thickly-set calcareous needles; the entire skin of *Polycera* and some other Nudibranchiates is studded with analogous ramified spiculæ.

The shell results from the metamorphosis and calcification of cells deposited in layers beneath the epidermis, in the situation of the rete-mucosum in the human integument. In *Limax* and *Clausilia* the first trace of the rudimental shell is in the form of crystals of carbonate of lime in the substance of the mantle. In most Univalves it is the result of calcification of the nucleated cells of the outer layer of the mantle, and especially of the thickened anterior border. The first-formed part of the persistent shell is called the “nucleus;” the succeeding layers are not, however, formed around this, but are added to the inner surface of the circumference of the previously-formed parts; and the proportions in which the new-formed layers extend beyond their predecessors determine the figure of the future shell.

In some Gastropods, at certain seasons, the margin of the mantle in which the shell-forming process is most active, extends outwards at an obtuse or right angle to the last-formed margin of the shell; and after having formed a calcareous plate in this position, the mantle extends in the ordinary direction, increasing the length of the shell, and is again similarly extended at a right angle with the

Gastropoda.

last-formed part. It is to this periodical growth of the mantle, and plethoric condition of the calcifying vessels, that the ridges on the exterior of the shell in the wentle-trap (*Scalaria pretiosa*) and harp-shell (*Harpa ventricosa*, fig. 85) are due. Should the margin of the mantle, instead of being uniformly extended, send outward a number of detached tentaculiform calcifying processes, these will form a row of spines corresponding in length and thickness to the softer parts on which they are moulded; and as the calcification of the processes proceeds, the spines which were first hollow become solidified, and finally soldered to the margin of the shell.

This development of pallial calcifying processes or filaments, and of the resulting spines, likewise alternates with periods of the ordinary increase of the shell; and thus its exterior surface may become bristled with rows of spines, as in the *Murex crassispina*. The periodical excretion of the excess of calcareous matter in the blood is greatest in the carnivorous Univalves.

The simple form of univalve shell is the cone, which may be much depressed, as in the genus *Umbrella* (fig. 58), or extremely elevated and contracted, as in *Terebellum* (fig. 89), or of more ordinary proportions, as in the limpets (*Patella*). The apex of the cone is always oblique and eccentric; directed, in limpets, towards the head, but in other Gastropods towards the opposite extremity of the body. The conical univalve shell is generally spirally convoluted, sometimes in the same plane,—e.g., *Planorbis*,—but more usually in an oblique direction, as in *Triton* (fig. 50). The apex of the shell *a* is formed by the nucleus, or the part which was developed in the egg; it is mammillated in *Fusus antiquus*. The spiral turns of the shell *ww* are called “whirls,” the last, *w*, *ac*, being the “body-whirl.” The lines or grooves formed by their junction are the “sutures” *s*, *s*. The “whirls” above the body one form the “spire” of the shell, *pc* to *a*.

As a general rule, the spiral Univalve, if viewed in the position in which its inhabitant would carry it were it moving forwards from the observer, is twisted from the apex downwards from left to right, the spire being directed obliquely towards the right; but in a few genera,—e.g., *Clausilia physa*,—the shell is twisted in the opposite direction, when it is called “reverse” or “sinistral.” Some individuals of *Butinus partula*, and *Pupa*, and a few marine species, as *Fusus sinistrosus*, are sinistral. The part around which the spiral cone is wound is termed the “columella;” it is exposed by removal of part of the shell in fig. 50, *o*. This central pillar is sometimes simple, sometimes grooved, sometimes plicated; in some shells it is solid, in some hollow, as in *Solarium* and *Dolium* (fig. 49), where the narrow elliptical aperture of the columella is seen to the left of the wide shell-aperture; it is termed the *umbilicus*. In *Solarium*, as in *Philippia*, the apex of the shell is inverted, and can only be seen by looking into the umbilicus.

The wide aperture which forms the base of the spiral Univalve is bounded by an “outer-lip” (fig. 50, *pc*, *ac*) and an “inner lip;” the latter offers a smooth convex surface, over which the foot of the Gastropod glides to reach the ground. In many Univalves, including most vegetable-

feeders, the aperture of the shell is entire; in others it is interrupted, the left side being formed only by the “body whirl;” or the “peristome” (as the margin is called) may be broken by a notch, like that which separates the outer lip from the umbilicus in fig. 49, or it may be perforated by one or more holes, or a portion of it may be produced into a canal or siphon (*ac*, fig. 50); this is sometimes termed the “anterior canal,” and the notch or hole at the opposite end of the peristome is called the “posterior canal” *pc*. These modifications are important, on account of the constancy of their relations to certain conditions of the respiratory organs. Thus all the Pectinibranchiate Gastropods, in which the water is conducted to the shell by a muscular tube or siphon, have the margin of the aperture either notched or produced into a canal; and the posterior channel (fig. 50, *pc*) is anal in its function (*Triton*, *Strombidæ*). Sometimes it is represented by a slit (*Scissurella*), or it is a tube (*Typhis*), or a perforation (*Fissurella*), or a series of holes, as in *Haliotis*.

The relations of these modifications of the univalve shell, which anatomy has made known, enable us to judge, from a fossil shell, of the nature of the medium of existence, of the respiratory medium, the food and habits, of its extinct constructor. The Gastropods which first appear in the Palæozoic strata have entire mouths; the siphonated species are not found lower than the Lias, and they go on increasing in numbers in and from the Tertiary series to the actual sea-shores.

In some of the Gastropods the shell consists of one piece, as in fig. 58, when it is termed an “inopercular Univalve;” but the aperture of the shell, in the majority of the species, is closed by a lid or plate, attached to the back of the foot, and called the “operculum” (fig. 86, *f*). This lid is sometimes calcareous, forming a second shelly plate, but it more frequently consists of an albuminous membrane only, or is horny, thus presenting the condition which the shell itself manifests in certain genera, as *Limax* and *Aplysia*; the inner surface is marked by a muscular impression, but unlike that on the shell, and whose lines bear no relation to the external lines of growth. Some opercula increase by the addition of matter to their entire circumference, and these are either “concentric,” as in *Paludina*, or “eccentric,” as in *Amphullaria* and most of the Pectinibranchs. Other opercula grow by the addition of matter to part of their circumference, and these are either “spiral” or “imbricate.” Spiral opercula may be either “paucispiral” (*Litorina*, fig. 52), or multispiral (*Trochus*, fig. 55). In the “imbricate” or lamellar opercules (*Purpura*, fig. 54), the layers of growth succeed each other in a linear series, and the nucleus is marginal. When the nucleus is apical or in front, as in *Turbinellus* and *Fusus* (fig. 53), it is said to be “unguiculate” or claw-shaped; when it has a projection, as in *Nerita* (fig. 51), it is “articulate.” No operculum presents an annular form. Deshayes figures the operculum of *Solarium patulum* as composed of many distinct and spirally-disposed lamellæ. Mr E. Layard has discovered a similar complex operculum in the *Catulus Austenianus*, a little Univalve of Ceylon. In *Torina straminea* the operculum is thick, horny, circular,

Gastropoda.

at the base, which is as large as the mouth of the shell, and concave externally. The rest of the operculum is produced conical, and of many whirls (fig. 56).

As the operculum sometimes varies in structure in the same genus, being horny in some species and shelly in others of *Ampullaria* and *Natica*,—as it is present in some volutes, cones, mitres, and olives, and absent in other species of these genera,—and as some genera in a natural family, e.g., *Harpa* and *Dolium*, among the Buccinoids, are without an operculum, whilst the other genera of the same family possess that appendage,—it obviously affords characters of secondary importance in classification. In *Lithedaphus* (*Calyptraea*) *equestris*, the whole base of the foot secretes a calcareous plate, which is cemented to the rock; and the shell appears to consist of two valves. In the *Chiton* (figs. 72 and 73), the shell is divided into eight symmetrical pieces, arranged like scales upon the back. The first of these is the smallest, the last the longest, and most approaching the circular form. In the interior of the shell the muscular impression is usually crescentic, with the horns turned towards the head of the animal.

Most univalve shells are composed of three strata, which differ in the arrangement of the calcareous particles. The innermost layer is nacreous in the fucivorous Univalves,—e.g., *Patella*, *Haliotis*,—and resembles enamel in the marine species. In *Cassis rufa* each layer is composed of many laminae, which are perpendicular to the plane of the main layer; and each lamina consists of a series of prismatic cells, adherent by their long sides. The laminae of the outer and inner sides are parallel to the lines of growth, while those of the middle layer are at right angles to them. In the cowries (*Cypraea*) there is an additional layer, which is nacreous, and formed by the overlapping mantle-lobes (fig. 48, *h*, *h*) when the animal has attained its full growth. Such shells are called “cameo-shells,” these ornaments being formed by the removal of one layer, and the carving of the next. Hunter¹ discovered that the molluscous inhabitant of a shell had the power of absorbing part of its dwelling. This property, which is now generally recognised, is well illustrated by the thinning of the parietes of the internal whirls of the *cones* and *olives*, from which two out of the three layers of which they were originally composed may be observed to have been removed. The absorption of shell is also illustrated by the removal or smoothing down of the spines of the rock-shells (*Murex*), as the growing whirl expands and overlaps its predecessor by the flattening of the inner lip of the mouth of the *Purpura*, by the widening of the focal aperture of the *Fissurella*; and it gives rise to various other modifications in the form and structure of shell in the progress of growth.

Another change of form is due to the physical decomposition or destruction of a part of a shell during the lifetime of the inhabitant. This occurs to the apex of certain Univalves after the shell has been excavated by the original occupant in the widening and lengthening the shell to accommodate it to an increase of bulk. Such shells are said to be “decolated,” as, for example, the *Bulinus decollatus*, *Cerithium obtusum* (fig. 79).

The inhabitants of univalve shells dispose in different ways of that part of their calcareous abode which they evacuate in the progress of growth. In the decolated shells the vacated space is walled off, prior to its abrasion, by the formation of a thin nacreous plate. In the *Vermetus gigas* the vacated portion of the tube is retained, and successively partitioned off; a series of concave plates or septa being thus developed. In the *Magilus antiquus* the posterior part of the shell, as the soft parts move forwards, is progressively

Fig. 56.

filled up with a dense, solid, subtransparent, crystalline deposit of carbonate of lime.

Univalves which inhabit rocks upon which surf-waves are ever breaking have stronger and denser shells than those that live in calmer seas, or in sandy and muddy bottoms. The shells of air-breathing Mollusks, which, as a rule, are thinner than those of marine species, exhibit analogous effects of external influences. The shells of the burrowing *Bulini*, e.g., are colourless and subtransparent; but the shell is vividly coloured in the species inhabiting plains with scanty vegetation and much exposed to solar light. The shells are largest and thickest in the arboreal *Bulini* of tropical forests, which live amongst an abundance of decaying vegetable matter.

The part of the mantle which invests the viscera in the conchiferous Gastropods—that behind letter *i* in fig. 49—is smooth, thin, and subtransparent, resembling the sac of a hernia, which, with the viscera themselves, appears to have escaped from the common muscular integument of the body. This “visceral mass,” as it is termed, is lodged in the upper part of the cone of the shell, the spiral turns of which it follows. The head (fig. 49, *ab*) and foot *d* of the animal can be protruded from the mouth of the shell, and be retracted within its last whirl, by the action of a muscle which has its fixed point in the columella of the shell. This retractor, which is attached to the operculum, seems to answer to the posterior retractor of the foot in Bivalves, much better, at least, than to the great adductor muscle. The form and size of the shell-aperture correspond with, and indicate the size of, the foot. In the pectinibranchiate Mollusks, which are the chief fabricators of the beautiful turbinated shells of the conchological cabinet, the foot is attached to the anterior part of the body by a narrow base, as in *Rostellaria* (fig. 88, *d*), whence they have been termed by Lamarck *Trachelipods*.

The primitive muscular fibre is smooth in all Gastropods. The primitive fasciculi have often numerous nuclei scattered through them, and will illustrate Kölliker's beautiful discovery of the nature of the smooth organic fibre as a much elongated cell-wall. The cutaneous muscular layer consists of oblique longitudinal and transverse fibres, intimately united with the corium. Upon the ventral surface it becomes very thick, and forms a long disc called the “foot,” marked *d* in all the figures of the *Encephala*. The fibres of this part contract successively, so as to form wrinkles or transverse waves, following each other from behind forwards, whereby the disc glides over solid bodies or the surface of water. The circular foot of the limpet is used as an adhesive sucker. In some species it expands to a great breadth. In *Siphonotus*, *Gasteropteron*, and other Tectibranchs, it develops lateral swimming lobes, which are analogous to the fins of the Pteropods. In many Gastropods the foot is extended lengthwise, and more or less cleft transversely, as in *Phorus* (fig. 78) and *Rostellaria* (fig. 88). The anterior division *d* forms the chief creeping disc; the posterior one *e* supports the operculum *f* when this is developed. The posterior lobe of the foot in the inoperculate *Harpa* is said to separate spontaneously when the animal is irritated. In *Atlanta* (fig. 65, *e*) it is compressed, but supports the operculum *f*. It seems also to form the tail in the beautiful *Carinaria* (fig. 70, *C*), in which the middle part of the foot is reduced to a compressed fin-shaped lobe (fig. 70, *B*) supporting a small suctorial disc *d*. This Mollusk and its allies, hence called *Heteropoda*, swim on their back with their reduced locomotive organ upwards. In most Gastropods the tentacles, buccal mass, and penis, have their special retractor muscles. The opposite extreme of development of the foot is presented by some of the *Neritacea*. The coriaceous foot of

Gastropoda.

¹ Phil. Trans., 1785, p. 343.

Gastero-
poda.

the burrowing *Natica* (fig. 80, *a*) is much developed anteriorly for perforating the sand, and can be reflected so as to protect the tentacle in that act. The sides *d* are produced for locomotion in water. The hind part of the foot *h* is expanded so as to cover the shell like a mantle-lobe.

In the living *Cypræa* (fig. 48) and *Ovulum* (fig. 81), the mantle-lobes *h, h* are observed to be in almost constant tremulous motion; but the most vigorous muscular efforts in Gastropods are those of the foot, combined with the retractor-shell muscle. The strombs and scorpion-shells thereby progress by successive jumps. The active olives can turn over when laid on their back, and bury themselves in the sand as the tide retires. The periwinkle advances alternately the sides of its longitudinally-indented foot; *Buccinum arcularia* defends itself by its dentated operculum.

At the grade of the Molluscous organization which the *Gasteropoda* have reached, their capabilities and spheres of action become more extended and diversified than in the *Pteropoda* and *Acephala*; some are terrestrial, some arboreal; whilst the more numerous aquatic species are endowed with power to attain, subdue, and devour organized matter, dead and living. The nervous system of the Gastropods is accordingly not only more complex and concentrated—not only subordinated to better developed masses in connection with organs of special sense and exploration,—but it offers greater variety in its general arrangement, and especially in the position of its ganglions, than in the Lamellibranchiate class; and with these modifications, considerable differences in the outward configuration of the body are associated. A few Gastropods, for example, are symmetrical, more or less flat, or depressed; others are compressed; the majority are contorted, and lose their symmetrical form in an oblique twist. There are other diversities of organic structure which more immediately affect the condition of the nervous system, for some species possess both eyes and tentacles; whilst others are blind and akerous.

The nervous system has a distinct fibrous neurilemma, often charged with pigmental cells. The ganglion-cells are often pedunculated, and have usually a very large nucleus, composed of obscure granules, in the midst of which are two or four transparent nucleoli. Such cells form the sole contents of the neurilemmal canal at some parts of the nerves. (Lewes.) The central part of the system surrounds the œsophagus, and consists of different parts, of which that placed above the tube, and which usually includes two contiguous ganglia, is called the brain (fig. 70, *u*).

In the limpet (*Patella*) and bubble-shell (*Bulla*), we find that the cerebral ganglions, as in the Bivalves and Pteropods, are still distant from each other, and situated at the sides of the œsophagus, connected together by a nervous chord or commissure, which arches over that tube; from these ganglions two nerve-trunks proceed backward on either side; the median and superior pair pass along the sides of the œsophagus, converge, and meet below to form a pair of ganglions in close contact with one another, which supply the foot; these are evidently homologous with the bi-lobed pedial ganglion of the *Mytilus*. The lateral and inferior filaments pass downwards to join two widely-separated branchial or splanchnic ganglions, homologous with those situated on the posterior adductor in the *Mytilus*. There is, however, a considerable difference in the relative positions of the pedial and branchial ganglions in the limpet; the latter have advanced into close contiguity with the pedial ganglions, and are connected with them by the same transverse chords, which in *Pecten* and *Mytilus* serve merely to bring the branchial ganglions themselves into mutual communication. The position of the cerebral ganglions varies according to the degree of extensibility of the mouth and œsophagus. Thus in the snails (*Helix*) they are placed above the mouth; in *Carocolla* at the commencement of

œsophagus; in the whelk (*Buccinum*), near the end of that tube; in the *Purpura* beyond the stomach.

As a general rule, we find that the superior ganglions give off tentacular, ocular, and buccal nerves; whilst the inferior masses are the centres of the muscular, respiratory, and visceral internunciate chords. In the *Carinaria* (fig. 70), the superior or cerebral ganglions are marked *u*; they supply the eyes *C*, the tentacles *b*, the acoustic sacs *u*, and complex parts of the mouth; the buccal ganglions, situated above the glottidium *a*, and developed upon the buccal nerves, may well be deemed the centres for the reception of such degrees of smell and taste as the Mollusk may enjoy. We have here, therefore, indisputably the centres of the nervous system which are analogous to the olfactory, optic, and acoustic divisions of the brain of *Vertebrata*;—Who may say that they are not also the rudimental homologues of such? Upon either basis the part of the Mollusk “above” or “dorsad” of the digestive canal is thus defined.

With a difference so great in the disposition of the locomotive organs and muscular masses in the Vertebrate and the Mollusk, corresponding differences in the ordinary excito-motory nervous centres must be looked for. In the *Carinaria* they are situated at *v*, above the base of the compressed foot *B*; they are connected, as in *Mytilus* by long commissural chords with the cerebral ganglia, and by a short, thick commissure with each other; thus completing a wide and loose œsophageal ring. Nerves or commissural chords pass from both the cerebral and pedial ganglions to the splanchnic or branchial ganglion *x*, situated, like the pedial, below the alimentary canal, and supplying that canal, the liver, heart, branchiæ, and genital glands.

In the spiral Pectinibranchiate Univalves, where the branchiæ and their nerves are twisted to the left side, it is the left branchia which is atrophied, while the right one is of large size. The nerves are similarly affected; the left branchial one being filamentary, whilst the right is a large chord, and has the branchial ganglion developed upon it.

The principal œsophageal ganglionic circle, in most Gastropods, more closely surrounds the gullet than in *Carinaria*, and is defended by a thick membrane, which, in the large Tritons, assumes almost a cartilaginous hardness. A coloured pigment is not unfrequently found occupying a position analogous to that of the arachnoid, between the dense outer membrane and the ganglions. In the *Limnea* and *Planorbis* this pigment gives to the ganglions their orange or roseate hue.

Amongst all the observed diversity in the number, size, and position of the nervous masses of the Gastropods, certain ganglia are obviously homologous with those which have received determinate names in the Lamellibranchiate Mollusks. The branchial or splanchnic ganglions (figs. 18 and 80, *x*) receive impressions from, and transmit them to, the gills, heart, and other viscera; they communicate with the brain, and either through that centre, or by more direct connection with the pedial ganglions, associate the circulating and respiratory forces with all other parts of the body. In the Gastropods which have great expanse of soft mucous integument exposed,—as, e.g., *Aplysia*, *Umbrella*,—accessory small ganglions, supplying such integument, are developed, which are in more immediate connection with the splanchnic ganglions. The pedial ganglions are more commonly distinct than in the Bivalves; and the two divisions are, in some Gastropods, wide apart, in consequence of the great breadth of the foot; in most Gastropods the acoustic sacs receive, as in Bivalves, their nerves from the pedial ganglions. The cephalic ganglions assume the character of optic lobes, concurrently with the constancy and better development of the eyes. Even when the organs of vision are more than usually minute, or are wanting, these ganglions are always larger than in the *Acephala*, and more decidedly superior in position; they supply also the acoustic vesicles in many

Gastero-
poda.

Gastropoda.

Gastropods, *e.g.*, in the whole order of *Nucleobranchiata*, and in some *Nudibranchiata*. The cephalic ganglions, when separate, are united by a thicker communicating chord, and are larger, in proportion to the nerves given off from them, than in the *Acephala*.

Soft, lubricous, and irritable as is the exposed skin of Gastropods, it would seem to possess a very low degree of true sensibility. Baron Férussac affirms that he has seen a slug allow its skin to be bitten by others, and, in spite of large wounds thus produced, it has manifested no sign of pain. Species of *Eolis*, in confinement, will devour each other's branchiæ, which may be reproduced. The vascular inferior surface of the foot may take cognisance of the character of the surface over which it glides; but the special organs of the tactile sense are the tentacles or "horns," which project from the lateral and upper parts of the head. It is most probable that, with the exception of the cephalic ganglia, the functions of the nervous centres are limited to the automatic reception and reflection of stimuli, like those of Hartley's first class of vibrations in man, depending on nervous influence "which is detached down the motory fibres before reaching the brain."¹

The common snail offers a fair type of the digestive system of a Gastropod. In fig. 63, *a* represents the dentated horny jaw which arms the upper lip; *h* the large white salivary glands that spread upon the sides of the wide gullet; *f* is the stomach; *g* a cæcal production which may represent the rudiment of a pancreas; *u* is the intestine, the part traversing the respiratory chamber, and commonly called rectum, laid open, terminating at *l*; *i*, *i* show the lobes of the liver. That typical bend of the gut, whereby its outlet is brought into communication with the respiratory and renal chamber is also illustrated in fig. 65, at *o* (*Atlanta*); and again in fig. 70, at *no* (*Carinaria*); the nearer approach to the straight course shown by the intestine of *Doris* or *Firola* (fig. 71, *mo*), is an exceptional departure from the Molluscous type, and is due to an equally exceptional position of the breathing organ.

Other well-marked modifications of the digestive apparatus will be noticed in connection with the species of *Gastropoda* that may present them. The blood of the Gastropod is often opalescent, with a few colourless corpuscles or cells having an indistinct granular nucleus.

The auricle is divided in *Fissurella* and *Chiton* as in *Haliotis*. Both auricles, however, equally receive the oxygenated blood from the respiratory organ, as does the single auricle in *Atlanta* (fig. 65, *x*), in *Helix* (fig. 63, *e*), and in all the other Gastropods. The ventricle (fig. 63, *p*) propels the blood to the viscera and muscular system of the body; and the heart is situated on the right side of the back in the *Pulmonata*, most *Tectibranchiata*, and the dextral *Pectinibranchiata*. It is on the opposite side in *Ancylus*, *Haliotis*, and the sinistral Gastropods. It is to the left of the dorsal median line in *Carinaria*, and near the hinder end of the body in *Firola*. The heart has a distinct pericardium in all Gastropods, save the *Apneusta*, where it is at least not clearly defined. The aorta, continued from the apex of the ventricle, divides into two principal branches in most of the Gastropods. The auriculo-ventricular aperture is usually defended by two semilunar folds (fig. 63, between *o* and *p*). The aorta at its commencement is frequently strengthened and enlarged by a muscular layer similar to the *bulbus arteriosus* in fishes, and which, in the *Aplysia*, is continued beyond the origins of the primary branches of the aorta. The ramifications of the aorta, as in crustaceans and insects, are sooner or later lost in veins which expand to form sinuses,

occupying the lacunæ of the viscera and other organs of the body.² The anterior aorta terminates,—*e.g.*, in *Patella*, *Triton*, *Haliotis*,—in a large lacunar sinus, containing the brain, the salivary glands, the œsophagus, and retracted tongue. The resumption of the normal vascular character by the venous system is more or less sudden, and is best exemplified near the respiratory organ (fig. 63, *nn*), upon which such venous trunk ramifies like an artery, without any interposed branchial or pulmonic heart. The large venæ cavæ of the *Aplysia* are perforated by minute apertures, communicating with the great sinus that lines the cavity of the abdomen; and the exterior of these veins is provided with decussating muscular fibres, which probably regulate the diameter of such communications.

The diffused condition of the vascular system most prevails in those Gastropods in which the respiratory organs are least developed—*e.g.*, the *Apneusta*. In the rest of the class the general modifications of the respiratory organs are indicated by the characters of the orders already defined. In the terrestrial Gastropods the breathing organ has the form of the simple undivided vascular sac (fig. 62, *nn*), like the lung in the lowest air-breathing vertebrate animals. Its orifice *m* is on the right side near the head. The forms of the aquatic-breathing organ are as various as its position.

In most of the Nudibranchiate species the gills are tufted and ramified, as in the higher Annelides. They are penniform in the *Haliotis*, and pectinated in all the dioecious Gastropods (fig. 77, *i*), as the name of their order indicates. In these they never exceed two in number, which are of unequal size; and the branchial chamber is usually prolonged into a siphon. In a few genera of amphibious Gastropods a pulmonary sac is combined with branchial organs; but in some of these,—as, *e.g.*, *Amphibola* (*Ampullacera*) *australis*,—the branchia are reduced to a mere gland. The branchial surface is ciliated in all the Gastropods, as is also the exterior surface of the body in the small fresh-water species.

As a compensation for the absence of gills, some *Apneusta* (*Actæon*, *e.g.*) have an aquiferous system, consisting of a reservoir filled with water, behind the heart, from which branched canals pass off in all directions, one of which, according to Vogt, opens on the right side behind the vent. Conspicuous aquiferous pores are situated at the centre of the foot in *Cypræa*, *Conus*, and *Ancillaria*; and at its margin in *Haliotis*, *Doris*, and *Aplysia*. Della Chiaje has described a similar system in many of the higher organized Gastropods. Besides the large and well-developed hepatic and salivary glands which are associated with the alimentary canal, certain fucivorous Gastropods present the simplest rudimental condition of the pancreas.

The follicular renal gland, sac, or surface, for the urinary excretion, communicates by the canal called its duct with the external surface near the anus, and by an opposite opening with the pericardial cavity. The sac has been seen to contract rhythmically in the transparent Pteropods and Heteropods, and may perform the same movements in other Encephala. Water seems to be freely admitted to this glandular cavity. In some Gastropods the duct dilates to form a small receptacle. A group of follicular glands, sometimes imbedded in a distinct glandular sac, is present in many species for the elimination of some peculiar and characteristic colour. The yellow liquid of the *Bulla*, and the famous purple secretion of the *Purpura*, are products of saccular modifications of this follicular gland, which is situated between the heart and liver. Numerous simple and scattered follicular glands lubricate the mantle with its characteristic mucus in all the Gastropods. In several

Gastero-
poda.

terrestrial species the median line of the foot is occupied by a straight canal, lined with ciliated epithelium, which ends in a large orifice beneath the mouth. On each side of this canal are rows of follicles, which secrete a granular mucus. A follicle excreting a similar mucus opens on the extremity of each dorsal or lateral lobe in the *Apneusta* which possess those appendages. "Some of the *Gasteropoda* can suspend themselves by glutinous threads, like *Litiopa* and *Lissoa parva*, which anchor themselves to sea-weeds (Gray), and *Cerithidea*, which frequently leaves its proper element, and is found hanging in the air. (Adams.) A West India land-snail (*Cyclostoma suspensum*) also suspends itself. (Guilding.) The origin of these threads has not been explained; but some of the *Limaces* lower themselves to the ground by a thread, which is not secreted by any particular gland, but derived from the exudation over the general surface of the body." (Lister; D'Orbigny.)¹ Some peculiar scent-follicles must exist in the garlick-snail (*Helix alliaria*). A species of slug, called *Phosphorax*, is slightly luminous.

Gastropods have the power of repairing injuries and of reproducing lost parts to a considerable extent. New tentacula soon grow to replace those which may have been amputated. When they support eyes, as in the snail, the organs of vision are reproduced also. The mouth, with the horny jaw, has grown again in this Gastropod; and when the snail has been decapitated, but with the œsophageal ganglions left behind, the head has been restored.

GASTEROPODA MONŒCIA.

ORDER I.—APNEUSTA.

No distinct respiratory organs. No shell (in the adult state).

Certain soft-bodied, subelongate, subdepressed, vermiform, aquatic animals, with a soft mucous ciliated integument, devoid of heart and respiratory organs, have been placed in the Articulate province of the animal kingdom, and therein have been associated with the *Annelides*, or with the *Entozoa*, or have been kept apart in an intermediate class, under the name of *Turbellaria*. In some of these worms (fig. 1) the alimentary canal, commencing by an evertible proboscis, sends off numerous branched blind-tubes, which radiate into the surrounding parenchyme. The œsophagus is surrounded by a nervous collar, developing two œsophageal ganglia, from which the nerves are sent off to the body. Some species have two cephalic tentacles (*Planaria tentaculata*; *Physanoxoon*, Grube). The ciliated skin appears to perform the function of respiration. No heart has been detected. The male and female sexual organs are combined in the same individual.

Similarly-shaped small marine animals, with a ciliated soft integument, equally devoid of heart and branchiæ, with the nervous system, the digestive and the generative organs, organized according to the same type as in the above-cited *Turbellaria*, have been placed in the Molluscous province. Such, e.g., are the species of *Rhodope*² and *Acteon*. The transition from these abbranchiate and acardiac worm-like animals to the Eolidians, which have a heart, but are without gills,—*Calliopea*, e.g. (fig. 2),—and from these to the true Nudibranchiates,—*Doris* and *Tritonia*,—is so close, that in drawing the line of demarcation in the series progressing from the Trematode Entozoa, through the *Planariæ* upwards, we define the Molluscous boundary as

arbitrarily as in the series progressing from the *Bryozoa*, through the *Tunicata*, to the same great province of the animal kingdom.

If the diffused and ramified type of the alimentary canal were taken as a character of *Turbellaria*, as contradistinguished from these Mollusca, we should find it in some, —e.g., *Eolis* and *Calliopæa*,—associated with a distinct heart; and in others,—e.g., *Elysia*,—associated also with a respiratory organ of the type of that of the pulmonated Mollusks. If we were to require definitely-developed respiratory organs as a title to admission into the Molluscous province, we must exclude true Gastropods, like *Glaucus* and *Calliopæa*, which are nevertheless too closely allied to *Scyllæa* and *Doris* to be placed in a distinct primary division of animals from them.

For those naked Gastropodous Mollusks in which the ramifications of the alimentary canal take the place and discharge the functions of a liver, and in which, although there may be productions of the skin simulating the more localized branchial processes in higher Gastropods, those productions receive gastro-hepatic cæca, not branchial vessels—for the reception of such low-organized Mollusks—an order or sub-order is requisite, for which the term *Apneusta* ("gill-less") may be retained. The order may be characterized as one of "Naked Gastropods, hermaphrodite, marine, without distinct respiratory organs; alimentary canal with gastro-hepatic ramifications; anus dextral. The species often swim on the back, with the foot supine."

Genus RHODOPE, Köl liker.—Body naked, smooth, subdepressed, without tentacles; organs of circulation unknown. The comparatively simple form of the peculiar digestive appendages of this species³ is an instructive one. Had it first been observed, instead of the more complex and ramified condition of the same parts, as in *Calliopæa*, it most probably would not have been mistaken for a "gastro-vascular apparatus,"⁴ or have given rise to the ideas originally broached and generalized under the term "phleboterism." The fry have no deciduous shell; they swim, like the *Turbellariæ*, by means of superficial vibratile cilia.

Sp. Rhodope veranii.—About 10 lines in length. Hab. Mediterranean.

Genera Lissosoma, Quatrefages; *Flabellina*, Ed.; *Phyllirhoë*, Péron.

Sp. Phyllirhoë Bucephalum, Lam.—Body oval, elongate, compressed, pellucid, without a trace of "foot;" coloured, with brown specks, head distinct, with two long, subulate, twisted tentacles; tail truncate, rounded; a pair of horny jaws; glottidium, with 3—0—3 teeth on the tongue-strap. Size of the animal varies from 8 lines to an inch. Hab. common in the Atlantic.

Six species of *Phyllirhoë* have been named and characterized; but the variability in the form of the soft contractile body, and in the superficial punctation and deeper-seated (visceral) coloration of the body, is such as to throw considerable doubt upon the constancy of the differences of colour which have been interpreted as specific.

Genus FUCOLA, Quoy.

Sp. Fucola rubra, Quoy and Gaim. (*Voyage de l'Astrolabe*, pl. 24, figs. 21, 22).

Genus AETHEON, Oken (*Elysia*, Risso).—Body subcylindrical, limaciform; head bordered by a depressed expansion, pointed behind; two subclavate non-retractile tentacles, with eye-specks behind them; vent, in some lateral and dextral, in others subdorsal; glottidium, with uniserial dental plate.

¹ Woodward, *Manual of Mollusca*, p. 103.

³ Köl liker, *loc. cit.*, pl. i., fig. 1.

⁴ Sur l'existence d'un appareil gastro-vasculaire chez la Calliope de Risso (E) Mollusque de la famille des Eolidiens, par M. H. Milne Edwards, *Annales des Sciences Naturelles*, 2d serie, tom. xviii., p. 330, 1842. It must be remarked, however, that the original discoverer of the gastro-hepatic canals in the Eolidians (Prof. Lowén), entertained from the beginning correct notions of their nature and functions.

Gastero-
poda.

Sp. *Actæon corrugatus*, Forbes and Hanley (*Brit. Moll.*, t. ccc., fig. 5).

Sp. *Actæon sinister*, Quatrefages (*Ann. des Sciences Nat.*, 1844, pl. 3, fig. 4; *A. viridis*, ib., pl. 3, fig. 2; *A. elegans*, ib., pl. 3, fig. 3).

Genus LIMAPONTIA, Johnstone.—Body oblong, depressed anteriorly, raised and rounded behind; head arched and keeled on the sides; eyes behind the carinæ; no tentacles; vent dorsal, sub-posterior.

Sp. *Limapontia nigra*, Forbes and Hanley (*Brit. Moll.*, t. ccc., fig. 4).

Genus CALLIOPÆA, D'Orb.—Body oblong, subdepressed; head forming a kind of round swelling circumscribing the mouth, with only two (posterior) tentacles, bearing eyespecks at their base; the foot slightly dilated anteriorly.

Sp. *Calliopæa Souleyetii* (fig. 57).—In this species the mouth is subterminal; the glottidium large, slightly protractile, and bearing a uniserial imbricated plate, with many denticles in each transverse row of the series. A slender, elongated, salivary follicle *a* opens on each side of the pharynx. The œsophagus is very short, being defined simply by the nervous collar, beyond which it dilates into a small ingluvies *S*, and afterwards into the stomach *e*, from the termination of which the short intestine and the gastro-hepatic canals diverge. The latter are four in number, are diverging, in two lateral pairs (one forwards, the other backwards, *c*), and sending off the branched gastro-hepatic follicles from their outer side. The heart is situated between the two diverging posterior gastro-hepatic canals; the wide auricle receives the blood from the diffused sinuses which have exposed it to the respiratory influence acting through the delicate integument. The aorta divides into two principal branches. The ovispermial masses are divided into separate rounded bodies with their several canals, which unite into a trunk traversing an ovoid glandular enlargement; beyond this the oviduct separates from the sperm-duct, the former terminating in a long convoluted uterus with glandular walls, and the latter terminating in a long, tubular, evertible penis.

Genus CENIA (Syn. *Ictis*), Alder and Hancock.

Sp. *Cenia Cocksii*, Forbes and Hanley (*Brit. Moll.*, t. ccc., fig. 6).

Genus PELTA, Quatrefages.

Sp. *Pelta coronata*, Quatrefages (*Annales des Sciences Nat.*, 1844, pl. 3, fig. 6).

Genus GLAUCUS, Forster.—Body elongate, slender, posteriorly filiform; foot linear, channelled; tentacles 4, conical; jaws horny; teeth in single series, arched and pectinated; gastro-hepatic cæca prolonged into three pairs of lateral, digitate, or palmate tegumentary sacs. Colour blue; length between 1 and 2 inches. Hab. Atlantic Ocean, between the tropics.

Mr Bennett, who captured some of these beautiful little pelagic Mollusks in Lat. 2. 26. N., Long. 19. 51. W., has recorded some interesting observations on their living colours, movements, and food, in the *Proceedings of the Zoological Society*, 1836, p. 113. The gastro-biliary and tegumentary productions, which some have called "gills," he terms "fins." As they floated upon the surface of the water (in the glass), the light silvery blue of the lateral parts contrasted with the deeper blue of the upper surface. This surface seemed to be most sensitive or irritable. When

Fig. 57.
Calliopæa Souleyetii.

touched the animal coils itself up, then dashes out into the linear form; again coils itself up, and so remains for a short period, apparently exhausted by its efforts. "But on the cessation of the irritating cause, the animal quietly resumed its original position, perhaps dropping one or two of its wearied fins, according as its own sensations of ease or comfort might dictate.

"When nothing irritated this tender Mollusk, it would remain tranquilly floating upon the surface of the water, with scarcely any movement but that which proceeded from the undulating movements of the digitated extremities of the fins, as well as an occasional slight twisting motion of the same organs.

"I felt much interest in the beautiful display of a circulating fluid on the dorsal surface of these animals, which was afforded me by the assistance of a microscope. Through the semi-transparent membrane of the back a fluid could be readily perceived close to the surface, evidently flowing in two directions, one taking a course downwards, and the other returning upwards; but I was unable to distinguish two distinct vessels for these separate actions.

"These animals seemed to be very torpid in their movements, although sometimes, when floating upon the water, they would be seen busily engaged in moving their fins about; but those actions were soon suspended, and their fins were suffered to hang lazily down, as if fatigued with the short exertion, which did not move them one inch about the glass of water; and even when the little indolent creatures did take the trouble to move themselves from one side of the glass to the other, it was effected by a tardy motion, stirring themselves first with one fin and then with the other, according as circumstances might require.

"I placed some small specimens of *Porpita* in the glass of water containing the *Glauci*, to observe if they would attack them; for some time one of the *Glauci* was close to a *Porpita*, and was even annoyed by the tentacula of the latter touching its back; yet the *Glaucus* bore this, although with the usual characters of impatience, yet without attempting to attack it. At last it seized the *Porpita* between its jaws; and by aid of a powerful lens, an excellent opportunity was afforded me of closely watching the devouring process, which was effected by an apparently sucking motion; and at this time all the digitated processes of the fins were floating about, as at other times when the animal was at rest. But I did not observe in one single instance that they were of any use to the animal, either to aid in the capture or to securely hold their prey when in the act of being devoured; for the animal seems to depend merely upon the mouth in capturing its prey; as in this and other instances, which I had opportunities of observing, they seized their prey instantly with the mouth and held it by that power alone, whilst by a kind of sucking motion the prey was devoured. The digitations may therefore only be regarded as appendages to the fins to aid the animal perhaps in the direction of its movements, as it was observed that they turned and twisted them about during the progressive motion (that is, when this tardy animal is pleased to progress, which appeared to me very rarely to meet with its inclination), as if in some way or other to direct the movements of the animal.

"The *Glaucus*, after eating the tentacles and nearly the whole of the soft under surface of its prey, left the horny portion, and remained tranquilly reposing upon the surface of the water after its meal, the only motion visible in the animal being the playing of the digits of its fins. The mutilated remains of the *Porpita* sank to the bottom of the glass.

"Soon after another *Glaucus* began a devouring attack upon another *Porpita* which had been placed in the glass, eating a little of it, and then ceasing after a short meal, occasionally renewing the attack at short intervals. On

Gastero-
poda.

Gastero-
poda.

examining the *Porpita*, which had been partially devoured by the ravenous *Glaucus*, I found the disc had been cleared of the tentacles and other soft parts; a small part of the fleshy portion only remaining upon the disc. Only one part of the horny disc exhibited any injury, and that appeared to be the place where the animal was first grasped by the *Glaucus*.

"When any of these animals came in contact with another in the glass, they did not display any annoyance, or coil themselves up, nor did they evince any savage propensities one towards the other; and they would often float about, having their digitated processes in contact one with the other, without exhibiting any signs of annoyance. Even when placed or pushed one against the other they did not manifest any irritation, but remained undisturbed, as in their usual moments of quiet repose.

"These animals soon perished. I could not preserve them for any length of time in the glass of sea-water, although the water was changed as often as it was thought necessary; the digitated processes of the fins were observed to shrink up on the death of the animal, and the process of decomposition rapidly took place, the whole body becoming a shapeless mass, having a bluish colour of deadly hue for a short period, and then became of a blackish or brownish-black colour. I have seldom seen a gelatinous animal which appeared so firm whilst in the water, that proved so speedily to decompose when removed from it. Even the beautiful purple of the back, the silvery or enamel of the abdomen, and the silvery blue of the sides, all speedily vanish, indeed instantly disappear, upon the death of the animal, as if it had been washed off; the expansive, delicate, and beautiful fins and digitated processes are no longer seen; they shrank up to nothing."

ORDER II.—NUDIBRANCHIATA, Cuvier.

Branchiæ extending more or less freely from various parts of the body.

Genera *Scyllæa*, *Doris*, *Thetis*, *Polycera*.

Genus SCYLLÆA, Linnaeus.—Body elongated compressed; foot long, narrow, furrowed longitudinally; head furnished with two retractile tentacles; back with two expansions or membranous and flexible wing-like lobes on each side; branchiæ penicillate, composed of filaments, scattered over back, especially crowded in the wings.

Sp. *Scyllæa pelagica*, L., Cuv. (*Ann. du Mus.* vi., pp. 416, 417, pl. 61, figs. 1-7; *Mollusq. Mém.* vi.; Blainv., *Malac.*, pl. 46, fig. 5).—This species attaches itself by its furrowed foot to *Fucus natans*, and is found in the Atlantic Ocean. The glottidium has a triserial rasp, with 24-1-24 teeth; the gizzard is armed with chitinous trenchant plates.

Genus TETHYS, L.—Body somewhat long, depressed, furnished anteriorly with a broad, funnel-shaped, fimbriated disc, behind which it contracts into a sort of neck; mouth probosciform, retractile. Two conical tentacles at the base of the disc retractile into broad cup-shaped sheaths. Apertures of generation and vent at the right side in the anterior part of body. Two rows of branchiæ at the sides of back; cirrose pectinate branchiæ alternating with smaller bundles.

Sp. *Tethys leporina*, L. (Rondelet, *Pisc.*, p. 526, *tertia leporis marini Species*; Cuvier, *Ann. du Mus.* xii., pp. 259-270, pl. 24, *Mém. sur les Moll.* vii.; Blainv., *Malacol.*, pl. 46 bis, fig. 9).—This species sometimes attains a foot in length. Hab. the Mediterranean.

Genus DORIS,¹ L., Cuvier.—Body oval, flat, or gibbous above, with abdomen flat, covered by a loose membrane, and plicato-marginate. Vent posterior, dorsal, in the mid line of body, surrounded by branched or plumed branchiæ disposed

in a circle. Apertures of generation at the right side. Two dorsal tentacles retractile within tubes, annulate with transverse lamellæ; two quasi-tentacular productions from near the mouth. Mouth armed with two horny plates (fig. 29, *a'*), united near the front, and having two projecting points; glottidium (fig. 29, *d'*) having lingual teeth numerous, central small, laterals similar, hooked, and sometimes serrated.

Genus TRITONIA, Cuvier.—Body elongate, subtetragonal or compressed, anteriorly rotundate, posteriorly acuminate; apertures of generation and of rectum at the right side, with vent situated behind the genital orifice. Two tentacles with branched filaments retractile into a sheath. Circular velum, tuberculated or digitated, in front of mouth. Two lateral jaws, acute, with margin denticulate. Branchiæ arborescent at the sides of back. Glottidium with triserial tooth-strap, one central, and numerous lateral teeth in a row.

ORDER III.—INFEROBRANCHIATA, Cuvier.

Branchiæ at the lower part of the sides of the body between the foot and mantle. The heart lies in these Mollusks in the middle of the body on the dorsal surface, and receives the blood from the gills placed on each side. Both "Prosobranchiæ" and "Opisthobranchiæ" are contained in this very natural group.

Genus PHYLLIDIA, Cuvier.—Body oblong, with a tuberculated mantle; head with four tentacles, the two dorsal retractile within a cavity; the other two labial; anus in posterior and middle part of back. (Cuvier, *Ann. du Mus.*, v., pp. 266-276, pl. 18; *Mollusq. Mém.* viii.)

Sp. *Phyllidia trilineata*, Cuvier; *Phyll. varicosa*, Lam., Cuvier, l. c., figs. 1-6; Blainv. *Malac.*, pl. 47, fig. 1).—Hab. Indian and Red Seas.

Genus PLEUROPHYLLIDIA, Meckel. (*Diphyllidia*, Cuvier; *Linguella*, Blainv.).—Body oblong, with ample mantle, acuminate posteriorly; head with two tentacles placed towards the back at the anterior margin of mantle; frontal veil with angle produced on each side; gills limited to the hinder two-thirds of the body; vent on right side, behind genital foramen.

Sp. *Pleurophyllidia lineata* (*Diphyll. lineata*, Otto, *Nov. Act. Acad. Cæs. Nat. Cur.* xviii.; Delle Chiaje, *Memorie* i., p. 128, tab. 10, figs. 12-20; Meckel, *Archiv. f. d. Physiol.* viii. 1823, taf. ii., figs. 1-7, s. 190-207).—Hab. the Mediterranean, and, according to Lovén, the North Sea also.

ORDER IV.—TECTIBRANCHIATA, Cuvier.

Branchiæ resembling pinnatifid leaves, restricted to one side, and covered by the mantle and a small shell, which is sometimes exposed. Most are phytiphagous; all have a complex gizzard.

Genus APLYSIA, L., Gmel.—Body oblong, limaciform, mostly margined by a broad velum reflected from the sides of the foot over the back; two contractile tentacles, conical, sulcated, in upper part of the head; two productions of the velum surrounding the mouth, forming as it were, a second pair of inferior tentacles; eyes sessile, in front of base of superior tentacles; branchiæ dorsal, covered by a production of mantle, including a flat membranoso-corneous or calcareous shell, and folded posteriorly so as to form an excretory siphon.

Sp. *Aplysia depilans*, L.—The tooth-strap of *Aplysia depilans* is broad, short, brown. Teeth brown, many on each diverging cross series; central tooth truncate, triangular, dilated beneath, with an arched base, and tridentate apex; lateral teeth 12-12, in an oblique line, each tooth arched, with the tip recurved, with three rounded

¹ *Doris*; see the critique of Cuvier on this name and on the confusion of this genus by Gmelin and others in *Ann. du Mus.* iv., p. 447 and foll.; *Mollusq. Mém.*, No. 5; also Rapp, Ueber das Molluskengeschlecht *Doris*, *Nov. Act. Acad. Cæs. Leop. Carol.* xiii., pp. 513-522, tab. 26, 27.

Gastero-
poda.

Gastero-
poda.

lobes on the lower edge; the crown of the anterior teeth worn, so as to leave the reflexed and lobed part. The gullet dilates into a large crop; the thick coats of the gizzard are beset with firm horny processes, some in the form of hooks, others of rhomboid crushing plates. Near the pylorus there is a long pancreatic cæcum.

The *Aplysia depilans*, or "sea-hare" of the Mediterranean, sometimes attains a foot in length. (For the other species of this singular genus, see Sander Rang, *Hist. Nat. des Aplysies*, Paris, 1828, folio.)

"The sea-hares are mixed feeders, living chiefly on seaweed, but also devouring animal substances; they inhabit the laminarian zone, and oviposit amongst seaweed in spring, at which time they are frequently gregarious. (Forbes.) They are perfectly harmless animals, and may be handled with impunity. When molested they discharge a violet fluid from the edge of the internal surface of the mantle, which does not injure the skin, has but a faint smell, and changes to wine-red. (Goodsir.) In old times they were objects of superstitious dread, on account of their grotesque forms, and the imaginary properties of their fluid, which was held to be poisonous, and to produce indelible stains." (Woodward.)

Genus DOLABELLA, Lam.—Operculum of branchiæ towards the posterior part of back, including a calcareous shell. Body mostly truncated posteriorly with an orbicular declining area.

Sp. *Aplysia Rumphii*, Rang (*Dolabella Rumphii*, Cuvier; Rumph, *Amb. Rariteitk.*, tab. x., fig. 5, tab. xl., fig. n the shell); Cuvier, *Ann. du Mus.* v. p. 437 and foll., pl. 39, figs. 1-4, *Moll. Mém.* 12.

Genus SIPHONOTUS, Adams.—Body elongated; gills covered by the mantle and shell; foot with the sides dilated into swimming lobes; respiratory orifice prolonged into a siphon. Shell nearly membranaceous.

Sp. *Siphonotus geographicus*, Adams.—Whitish-brown, covered with minute dark specks, and large, irregular, green, reticulated patches, margined with opaque white; under surface of foot of a bright yellow, left side of foot with a projecting lobe, which overlaps that of the opposite side; siphon of the mantle prolonged into a tapering, subcylindrical tube. Hab. Java Sea, among masses of floating sea-weeds.

Genus UMBRELLA, Chemnitz.—Body chiefly composed of a large, thick, tuberculated foot, deeply notched anteriorly; mouth (fig. 58, *a*) probosciform, retractile into the pedal notch, overhung by a small velum; tentacles two, with plicated cavities at their base; eyes sessile between the tentacles; genital orifice in front of the tentacles; excretory orifice posterior, tubular. Shell orbicular, almost flat, with a subcentral low apex.

Sp. *Umbrella mediterranea* (fig. 58).—The tooth-strap

Fig. 58.
Umbrella mediterranea.

of *Umbrella mediterranea* is broad, longitudinally plaited; teeth in numerous oblique series, each containing numerous small, closely pressed, compressed, sharp-edged, transparent teeth.

Genus BULLÆA, Lam.—Velum of head large, separated

from the mantle by a transverse furrow (fig. 59, *m*), which invests the shell *s*. Vent, orifice of generation, branchiæ, and heart placed at the right side. Foot broad, shorter than body, with the lateral margins *l* produced, but not enveloping. Tooth-strap with two or four series of sickle-shaped teeth. Shell thin, convolute, with aperture large.

Sp. *Bullæa aperta*, Lam. (fig. 59).—The tooth-strap of this species is thin and narrow, with brownish transparent teeth; two in each transverse row, close together at the base, long, slender, compressed, arched, nearly in half a circle, with the inner edge finely denticulated. The gizzard is armed with three long, partly horny, partly shelly plates. The eggs are in a single series, in long spiral gelatinous filamentary capsules. The fry are furnished with ciliated vibratile swimming lobes, and have a spiral, operculated shell.

Genus SCAPHANDER, Montf.—In this genus the shell is oblong, convolute, spirally striated, with the aperture much expanded in front; the spire concealed.

Sp. *Scaphander lignarius* (*Bulla lignaria*, L.).—The teeth are in two longitudinal series, claw-shaped; crenulate on the convex margin near the point, with a crest on the same margin near the base. The gizzard is provided with two large triangular calcareous plates, united together by strong transverse muscular fibres attached to their circumference, except at the upper part, where a third small oblong plate is interposed between the two lateral ones.

The *Scaphander lignarius* feeds upon the *Dentalium entale*; five of these have been found in the gizzard, with the shells partly crushed and digested.¹

Genus TORNATELLA, Lam.—Body ovate, white; head broad, notched in front, with a pair of eye-specks (fig. 60, *c*), and two retroverted tentaculiform lobes *h*; the foot has two small anterior productions *b*; slightly developed lateral lobes support the shell, and an opercular appendage *f*.

Sp. *Tornatella tornatilis*, Lam. (fig. 60).—Hab. British seas, in deep water.

Genus BULLA, Lam. (fig. 61).—Head in the form of a large disc *a*, truncate, and often mesially notched in front; produced above into lobes *b'*; laminated beneath, and sometimes with lateral appendages *b*; two subcentral

Fig. 61.
Bulla vezillum.

eye-specks; side lobes of the foot large. Shell ventricose, convolute, partially exposed; aperture long, lip sharp.

Bulla vezillum, Chemnitz (fig. 61) after Adams).—This most beautiful species was captured in sea-weed, in

Gastero-
poda.

¹ Madame Power in *Annals and Magazine of Nat. History* for November 1857.

Gastero-
poda.

about a fathom water, near Ambolan, Mindoro, by Mr Adams. The animal was of a delicate pink colour, with the cephalic disc and lobes, and the foot, edged with white and red. The foot, when not expanded for swimming, is folded upon the shell. The inner margin of the mantle forms a thick fleshy lobe, which partially fills the hind part of the shell aperture; the outer margin lines the outer lip.

Fig. 62 gives the character of the dentition in the *Bullidæ*, the central teeth being small and few, as in *Akera bullata*, or wanting; the laterals single, slender, and recurved.

Fig. 62.
Teeth of *Akera bullata* (magn.).

According to Cuvier, the cephalic lobes δ of the *Bullidæ*, represent the fused oral and dorsal tentacles. In the common "bubble-shell" (*Bulla Hydatidis*) they consist of a central stem bearing numerous lateral plates, and are conjectured by Mr Hancock to serve as olfactory organs.

ORDER V.—PULMONATA, Cuvier.

Part of the mantle-cavity forming a vascular air-sac or lung.

This well-marked order of Mollusks is treated of at length in the illustrated work of Baron Férussac, *Histoire Natur. des Mollusques terrestres et fluviatiles*, Paris, of which the first part appeared in 1819. M. Deshayes, after the death of Férussac, began the continuation, which was completed in 1851.

Most *Pulmonata* are terrestrial; those which are aquatic rise to the surface of the water to breathe. A few are naked; most are testaceous; and the latter are distinguished as having, or wanting, the operculum. The inoperculated Pulmonates have a tongue-strap, paved with rows of very numerous similar teeth, with broad bases; the operculated Pulmonates have a tongue-strap with arched rows of seven teeth, the median tooth differing from the three on each side.

Section 1.—INOPERCULATA, Férussac.

FAMILY I.—HELICIDÆ. (Snails.)

Shell external, usually well developed, closed by an epiphragm during hibernation.

Genera *Helix*, *Vitrina*, *Succinea*, *Bulinus*, *Achatina*, *Pupa*, *Clausilia*.

The common garden-snail (*Helix nemoralis*, L.) exemplifies the present family. The species selected by Bruguières from the wide Linnæan *Helix* to form his more restricted genus, have since been much subdivided by Conchologists. The following indicate some of the leading modifications of the shell:—

† Aperture turned upwards, dentate on each side.

Genus ANOSTOMA, Fischer, Lam.

Sp. *Helix ringens*, L. (D'Argenv. *Conchyl.*, pl. 28, figs. 13, 14; Blainv. *Malac.*, pl. 39, fig. 4.)—Hab. East Indies.

†† Aperture inclined downwards; shell at the periphery carinate or subcarinate, mostly depressed. Labrum often reflected, sometimes dentate.

Genus CAROCOLLA, Lam.

Sp. *Helix Lapicida*, L. (Pfeiffer, *Schn.* i., tab. ii., fig. 26); *Helix Carocolla*, L. (D'Argenv. *Conch.*, tab. 8, fig. D; Guérin, *Iconogr.*, pl. 6, fig. 1).—Hab. East Indies, &c.

††† Aperture inclined downwards. Shell rounded at the margin, most frequently subglobose.

Genus HELIX, Lam.

Sp. *Helix Pomatia*, L. (Sturm, *Deutschl. Fauna*, vi., Heft i.; Pfeiffer, *Schn.* i., tab. ii., fig. 9; Cuv., *R. Anim.*, ed. 2, t. iii., p. 40, *Moll.*, pl. 21. The Vineyard-Snail, le Grand Escargot).—The name *Pomatia*, from Πόμα, cover (*Cochlea opercularis*), was given to this animal on account of the closure of the aperture of the shell in winter that occurs in this and other species. In autumn the animal retracts itself within the shell, and then a false operculum (*epiphragma*) is

Gastero-
poda.

Fig. 63.
Helix pomatia.

secreted, which is pushed off in spring, when the snail again creeps out of its house. During the winter these snails in our temperate climate "hibernate," i.e., take no food, but lie torpid; in like manner, in tropical regions the species of this genus in the hot and dry months "æstivate," or fall into a similar state of torpidity.

The anatomy of this large species of snail has been admirably described by Cuvier, from whose monograph the preceding figure (fig. 63) is taken. The parts relating to the digestive, circulating, and respiratory systems have already been pointed out. The modification of the singularly-combined male and female apparatus, in this most highly developed of the monoecious Gastropods, calls for a more detailed notice.

The complexity and bulk of the combined organs in the vineyard-snail are truly extraordinary. The essential organs, testis and ovarium, are associated together in the form of a small compact gland (fig. 63, *g*), composed of many parallel cæca imbedded in the substance of a lobe of the liver *i*, and occupying the apex of the shell. Each cæcum consists of an external layer, producing ova, and an internal sac, folded in the first, producing semen.¹ The walls of

¹ Meckel, H., Ueber den Geschlechtsapparat einiger hermaphroditischer Thiere, in *Müller's Archiv für Physiologie*, 1844, p. 376.

Gastero-
poda.

these invaginated sacs are usually in contact, but become separated at the points where the ova push the ovarian sac outwards, and the sperm-cells the testicular one inwards. The common ducts from those series of combined sacs are also invaginated, the oviduct being external, the sperm-duct internal, and usually undulated. The testicular cæca and sperm-duct are lined with ciliated epithelium; this is not present in the ovarian sacs.

Both invaginated tubes *r* enter the albuminiparous sac *s*, and separate where they quit that part. There is a dilatation or sperm-reservoir where the sperm-duct quits the base of the albuminiparous sac, and this latter may be regarded as a more special dilatation of the oviduct, with follicular walls. The sperm-duct, enlarged and with more glandular walls *u*, now proceeds, with many short folds parallel with the uterus, to the base of the penis. This is a long and slender organ *v*, usually retracted and concealed within the visceral cavity, but, like the finger of a glove, capable of being everted and protruded externally. The so-called "uterus" *t* is a long canal, with transversely-PLICATED glandular walls, terminated by a vagina opening into the common genital vestibule, the external orifice of which is near the mouth of the respiratory sac, on the right side of the head. With the vagina there communicates the duct *z* of a small pyriform vesicle *z*, which is a sperm-reservoir for the fecundating element of another individual received *in coitu*. A small cæcum is developed from the duct in *Helix pomatia*, and a very long one in *Helix arbustorum*; the duct is short and simple in the slug (*Limax*). The genital vestibule receives the terminal outlets of two groups of branched cæca *x*, *x*, or "multifid vesicles," the function of which is unknown. But the complexity of the generative apparatus does not end here; the snail is provided with a pyriform muscular sac *y*, the aperture of which terminates close to the generative outlet. The expanded base or head of a slender conical calcareous style or dart is attached to the fundus of the sac: its sharp apex extends close to the orifice, and by the contraction of the sac it can be protruded outwards. With it the snails pierce each other's skin; and the function of this curious organ would seem to be to cause a preliminary excitement to the reciprocal union of the two androgynous individuals. The dart, like the epiphragm, is annually reproduced.

Of the rare *Helix vittata* (fig. 64), which inhabits Balamangan, Borneo, Mr Adams, its discoverer, remarks, that

Fig. 64.
Helix vittata.

the animal is of "a delicate subtransparent pinkish colour, the free lobes of the mantle moveable, and often extended from the fore part of the shell; eye-peduncles long, the truncatures for the eyes very broad, tentacles rather long and clavate; foot compressed, finely crossed with oblique lines, and margined inferiorly, the end with a large hollow muciparous follicle, ending below in a sharp, moveable, rather recurved process."

"This beautiful and singular species lives among the foliage of the low trees, about which it crawls with surprising rapidity, reminding one of the movements of the *Vitrina* more than those of the *Helicidae*." (*Zool. Samarang*, p. 60.)

FAMILY II.—LIMACIDÆ.

(Slugs.)

Gastero-
poda.

Shell rudimental, internal.

Genera—*Limax*, *Arion*, *Parmacella*, *Testacella*.

Genus *LIMAX*, Lam. (*Ground-Slugs*, *Path-Slugs*).—Body oblong, naked, convex above, furnished anteriorly with a coriaceous, subrugose mantle, and below with a longitudinal flat disc or foot, which is not distinct from the body; branchial cavity under the shield or small mantle, in the anterior part of back; respiratory orifice and vent placed in the right side; generative orifice beneath the right tentacles. The mantle in some contains a calcareous grit, in others a small shell; when alarmed, they withdraw the head beneath the mantle. At the hinder end of the body is a small aperture, from which adhesive mucous threads proceed. The slugs often climb trees in quest of the decaying vegetable matter on which they feed, and they lower themselves to the ground by means of those threads.

FAMILY III.—ONCIDIADÆ, Woodward.

No Shell.

Genera—*Oncidium*, *Vaginulus*, *Peronia*, *Oncidoris*.

The slugs (*Limaces*) and land-soles (*Arions*) of temperate climates are represented in the East by the *Oncidium*, *Veronicella*, and *Peronia*, as they are in the Western Hemisphere by the *Vaginulus*. The *Veronicella* lives upon the trees in the forests, and is active after showers; the *Oncidia* live on aquatic plants in marshes and ditches; while *Peronia*, like *Oncidoris*, lives among the stones on beaches, but, unlike the latter genus, above high-water mark, a little beyond the influence of the tide.

One species (*Oncidoris celtica*) is found on the coast of Cornwall, congregated in little groups, about a foot or two from the surface of the sea, where the waves break over them. They ascend and descend, so as to maintain their distance as the tides rise and fall; but will not bear long immersion in sea-water. (Couch.)

FAMILY IV.—LIMNEIDÆ.

(Pond-snails.)

Head with a short dilated muzzle; tentacles two, broad, short, compressed, not retractile; eyes sessile between their bases; mouth armed with an upper mandible; tongue-strap with teeth similar to *Helix*. Shell thin, horn-coloured; capable of containing the whole animal when retracted; aperture entire longitudinal; lip sharp, ascending towards the columella; apex sometimes eroded.

Genera—*Limnea*, *Physa*, *Ancylus*, *Planorbis*.

In the common pond-shell (*Limnea stagnatilis*) the apertures of the sexual organs lie far apart. Under the right feeler is the prepuce, everting the penis; under the respiratory aperture is the vulva, or that of the female organs. To this it is to be ascribed that, in copulating, one individual is connected with two others, one of which impregnates it, whilst the other is impregnated by it. In this way, hanging together, they often form long chains. Von Bæer has, however, observed self-impregnation also in *Limnea auricularis*. (Müller's *Archiv*, ii., 1835, s. 224.) The Limnean anatomy is well illustrated in Swammerdam, *Bijbel der Nat.* i., bl. 164–169, tab. ix., fig. 4; Cuvier, *Ann. du Mus.* vii., pp. 185–193, pl. x., figs. 2–11; *Mollusq. Mém.* No. 14; Stiebel, *Dissert. inaug. sistens Limneæ stagnatilis Anatomen*, Gottingæ, 1815, 4to, c., tabulis 2.

"The Limnæids inhabit fresh waters in all parts of the world; they feed chiefly on decaying leaves, and deposit their spawn in the form of oblong transparent masses on aquatic plants and stones. They frequently glide beneath the surface of the water, shell downwards, and hybernate or estivate in the mud." (Woodward.)

Gastero-
poda.

FAMILY V.—AURICULIDÆ, Woodward.

Mouth with a broad and short muzzle, tentacles two, cylindrical, the eyes sessile behind them; mantle-margin thickened; orifices as in the snails; foot oblong; sexes united; mouth with a horny upper jaw. Shell spiral, covered with horny epidermis; spire short, body-whirl large; aperture elongated denticulated; internal septum progressively absorbed.

Genera—*Auricula*, *Conovulus*, *Carychium*, *Marinula*, *Cassidula*, *Polydonta*, *Pedipes*.

Mr Adams remarks,—“The habits of this family are somewhat variable. *Marinula* affects salt water only, and *Pedipes* lurks in the cavities of rocks and under stones exposed to the sea. *Cassidula* is amphibious, having been observed crawling on a sandy bottom in clear water at a depth of nearly two fathoms, as well as in mangrove-swamps and on the sea-beach. *Curricula* and *Metampus* live in damp situations near the sea, and on the muddy banks of rivers. *Polydonta* inhabits moist situations in woods near the sea, but is wholly of terrestrial habits, living on decayed vegetable matter, and crawling about actively after showers of rain. *Alexia* and *Carychium* abound in salt-water marshes.” (*Zool. Samarang*, p. 55.)

Section 2.—OPERCULATA, Férussac.

“The operculated land-snails are exceedingly like periwinkles (*Litorinæ*), and chiefly differ from them in the situations they inhabit and the medium respired. They have a long truncated muzzle, two slender contractile tentacles, and the eyes are sessile on the sides of the head. The mantle-margin is simple, and the pulmonary cavity is situated on the back of the neck, and quite open in front.” (Woodward.) The sexes are distinct.

FAMILY I.—CYCLOSTOMIDÆ, Woodward.

Shell spiral, and spirally striated; aperture sub-circular, with a simple peristome; operculum spiral.

Genera—*Cyclostoma*, Lam.; *Pupina*, Vignard; *Helicina*, Lam.

Only one British species of *Cyclostoma* (*C. elegans*) is known, but upwards of 80 exotics have been characterized from the south of Europe, Africa, and Madagascar. Nearly half of these have the whorls spirally keeled, and have been subgenerically separated under the name of *Tropidophora*.

FAMILY II.—ACICULIDÆ.

Shell elongated, cylindrical, with a subspirally operculum, in most pellucid.

Genera—*Acicula*, *Geomelania*.

The two diœcious pulmonate families make a transition, in regard to generative characters, to the next great section of the *Gasteropoda*; but the modifications of the parts of the complex combined organs of the Androgynous Gastropods are manifold. In regard to their ultimate terminations or outlets, a common genital orifice is found in *Doris*, *Thetis*, *Bulinus*, *Clausilia*, and *Limax*, as in the *Helix* above described. In *Limnea* the sexual orifices are wide apart; in *Planorbis* and *Physa* they are situated side by side,—the male orifice in front, on the left side of the neck, behind the tentacle. In *Bulla*, *Bullea*, and *Aphysia*, the male orifice is under the right tentacle; the female one much further back. In *Doridium* the male orifice is beneath the left tentacle; the female one on the same side, but near the opposite end of the body. In *Oncidium* the female orifice is situated close to the anus, at the posterior end of the body; the male orifice is beneath the right tentacle. In all cases where the male and female organs are separate, a furrow may be traced from one to the other; the penis, when erected, projects from the male orifice.

¹ Gr., signifying an “odd or imperfect foot.”

² So called because the respiratory and digestive organs form a sort of nucleus on the posterior part of the back.

³ See also Leuckart, *Zoologische Untersuchungen*, Drittes Heft, Giessen, 1854, *Der Bau der Heteropoden*, pp. 1-68.

GASTEROPODA DICEIA.

Gastero-
poda.ORDER I.—HETEROPODA,¹ Lamarck.

(*Nucleobranchiata*, Blainville.)

Locomotive organ compressed, resembling a fin, but single and ventral in position; branchiæ, when distinct, pectinate and pinnate, packed in a small compass, with the heart in a dorsal sac or in a symmetrical shell. Sexes distinct. These Mollusks all live in the sea, and usually swim with the fin-shaped foot upwards and the back downwards. They progress rapidly by the vigorous movements of their compressed tails, or by a fan-shaped ventral fin; and adhere to sea-weed by a small sucker placed on the margin of the latter. Forskael, to whom we owe the first description of this family of animals, gave them the name of *Pterobranchia*. De Blainville, associating with them certain Pteropods, called the group *Nucleobranchia*.² The existence of distinct sexes was discovered by Lesueur, Laurillard, and Milne Edwards.³

There are two families of Nucleobranchiate Mollusks—the *Fiolidæ*, with large bodies and small or no shells, and the *Atlantidæ*, which can retire into their shells and close them with an operculum. Both animal and shell are symmetrical, or nearly so; the nucleus of the shell is minute and dextrally spiral.

Fig. 65.
Atlanta Keraudreni (magn.)

FAMILY I.—ATLANTIDÆ, Woodward.

The shell large enough to protect the body.

Genera—*Atlanta*, *Porcellia*, *Bellerophon*, *Cyrtolites*.

Genus ATLANTA, Lesueur.

Sp. *Atlanta Péronii*, Les. (figs. 66 and 67); *Atlanta Keraudreni*, Les. (fig. 68); *Atlanta gibbosa*, Soul. (fig. 69).—The soft parts of *Atlanta* are divisible into a “soma” and a “pallial” region. In fig. 65 the former or chief fleshy part of the body is out of the shell; the pallial or visceral part is in the shell, which latter is an appendage to it. The “soma” is divided into the cephalic A, pedial B, and the lid-bearing tail or operculigerous lobes e, f; the two latter having that distinct degree of development which characterizes the *Heteropoda*. The head, or cephalic lobe, includes the mouth-mass a, the tentacles b, and the eyes l; the foot is divided into the “fin” B and the “disc” d; the tail includes the “leaf” e (“expansion foliacée”), and the “lid” or opercule f, with its surface of attach-

Fig. 66.
Atlanta Péronii.

Gastero-
poda.

ment. The shell of the *Atlanta*, besides the beauty and symmetry of its shape, purity of colour, and delicacy of texture, is remarkable for combining two conditions of shell-tissue; retaining a large proportion of the mouth, or last-formed part, in a soft flexible quasi-cartilaginous state, the rest of the shell being vitreous. The whole is thin and translucent. It is suborbicular, compressed (fig. 68), and convolute on the same plane; umbilicate on each side, broadly keeled, and striated subtransversely. The whorls are usually three in number, and are visible in each lateral umbilicus; the last whorl, much larger than the rest, is that from which the keel is developed. This is a single plate, with a fine groove of uncalcified matter along its free border, which subsides towards the shell-aperture. The lid or opercule (fig. 67) is vitreous, transparent, very thin, and marked by transverse striæ of growth, of a shape conformable to that of the shell-aperture. The mantle includes the visceral mass, and lines the shell which it has developed. Round the base of the visceral mass it forms a broad fold corresponding with the shell-aperture, anteriorly into a large breathing-pouch. The thickened border of this pouch is provided with tufts of vibratile cilia, and in the species, —e.g., *Atlanta Keraudrenii*, in which the shell-aperture is canaliculate, the border is similarly produced (fig. 65, *h*), as in the siphonobranchiate Univalves.

For a knowledge of the anatomy of the *Atlanta* science is mainly indebted to MM. Eydoux and Souleyet, from whose beautiful illustrations of it in the *Zoologie of the Voyage of the Bonite* the scheme in fig. 65 is chiefly derived.¹ The viscera occupy the spire and spiral half of the last whorl of the shell; the rest of that whorl contains the branchial sac and mantle, and into it the whole of the soft parts of the animal can be retracted, and be there shut in by the operculum. In this respect the *Atlanta* differs from other Heteropods; and the opercule is a correlative peculiarity to the protective size and office of the shell.

The subspirial retractor muscle (fig 65, *h*) arises from the convexity of the innermost whorl, expands as it approaches the outlet, and then divides into fasciculi, which diverge to the head, to the foot-fin and foot-disc, and to the tail; the parts are retracted in the same order, the head being first pulled in. The mouth *a* is terminal, with a circular lip; the glottidium *a'* is covered by a tooth-strap supporting a median row of imbricated tridentate plates and lateral rows, each row including a transverse plate with a hooked apex and two sickle-shaped denticles; the teeth increase in size from before backwards; the glottidium is partially protruded by short protractor muscles, and retracted by antagonistic fibres; the dental plates being alternately raised, divaricated, and depressed in the alternate movements of the rasp-like organ. The secretion of two long cylindrical salivary glands *n* is poured into the beginning of the œsophagus. The œsophagus dilates into a fusiform preventriculus *m*, from which the alimentary canal, bending round the inner whorl, penetrates the liver, and expands into a subquadrate stomach *n*, receiving the wide bile-ducts; the intestine *o* is reflected upon the dorsal aspect of the stomach, passes forward into the branchial sac, and terminates there on the right side, at some distance from the anterior border of the mantle. The short intestine is lined

Fig. 67.
Atlanta Péronii.
and dilated

Fig. 68.
Atlanta Keraudrenii.

by ciliated epithelium. The chief mass of the blood, which, from the translucent delicacy of the tissues, seems to be diffused through the common cavity of the body, is contained in venous sinuses so disposed as to regulate the flow of the venous blood to the respiratory surface, to the filaments or laminae *i* of the branchial chamber *h*. Thence it is transferred and subjected to the action of the renal emunctories *q* before it enters the auricle *x*, which is at the bottom of the branchial cavity. The ventricle *s* distributes the depurated blood by two principal arteries,—one to the visceral mass, the other reflected forwards beneath the alimentary canal, and supplying the foot and the head.

The nervous system includes two cephalic or superœsophageal, two pedial or subœsophageal, and a small visceral ganglion; the acousticles are connected with the cephalic ganglia or auditory sacs.² The eye is lodged in its proper tentacle, whose clear convex end forms the cornea. The optic nerve, penetrating the inner wall, expands into a retinal ganglion, in front of which is a spherical lens; the ganglion and back part of the lens are covered by black pigment, and the whole is inclosed by a sclerotic which is continuous with the corneal part of the tentacular eye-sac. The acousticle has a small rotatory otolite. In the male the testis *w*, usually more or less lobulated, occupies, with the liver *p*, the spire of the shell. It contains spermatozoa and spermatozooids. Its duct communicates with a dark-coloured accessory gland *v*, and a glandular dilated part or vesicle *y*, whence the sperm-duct is continued a short way forwards, and terminates in a ciliated groove leading to the base of the penis *z*, which is attached to the right side of the body. In the female the ovary occupies a corresponding position to that of the testes; the oviduct is continued from the fore part of the ovary: it is wide and convoluted, and terminates near the vent in the pallial cavity. Of this genus, presenting the organization above defined, many species have been characterized, chiefly by modifications of the shell. In some—e.g., *Atlanta Keraudrenii*, Le-sueur (fig. 68)—the keel is continued to the aperture of the shell which is canaliculated anteriorly, with a corresponding siphonic modification of the mantle. In others—e.g., *Atlanta Péronii* (fig. 66)—the keel subsides before attaining the aperture of the shell, which is deeply fissured.

In a few species—e.g., *Atlanta gibbosa* (fig. 69)—the symmetrical form begins to deviate into the more common type of spiral Univalves; the shell of the embryo forming several obliquely spiral whorls before the particular generic type is resumed by the last large whorl of the adult. Thus the spire projects from the right side, leaving an umbilicus only on the left side; and the apex of the spire is turned forwards.

To this interesting type belong also the *Atlanta involuta*, E. and S.; *Atl. fusca*, E. and S.; and *Atl. turriculata*, D'Orbigny. Nomenclative naturalists have not been wanting in the imposition of distinct sub-generic names upon the groups of the genus.³

These small, delicate, and beautiful Mollusks are common in the high seas of tropical and temperate latitudes, floating or swimming by vigorous strokes of their fin above unfathomable depths. Such of their frail shells as may reach the bottom will form one of the few evidences of life that deposits from deep seas are likely to reveal; and certain delicate, finely-striated shells, analogous, if not allied, to *Atlanta*—such, e.g., as *Ecculiomphalus Bucklandii*, Portlock, and *Bellerophon bicarinatus*, Léveillé—have been found fossil in both Cambrian and Silurian rocks,—the most ancient

Gastero-
poda.

Fig. 69.
Atlanta gibbosa.

¹ The details given in the *Philosophical Transactions* for 1853, p. 36, are little more than confirmations of the facts made known by the able French naturalists whose anatomical labours are passed over, except in regard to "a small ganglion," which the writer states is "not figured by Eydoux and Souleyet," but which they nevertheless have not omitted to specify and figure in allied *Heteropoda*.

² The auditory vesicles were first pointed out in *Heteropoda* by Souleyet; *Annales Françaises d'Anat. et de Phys.*, tom. ii., 1841, p. 305;—afterwards by Leydig; *Anatomisch. Bemerkung. üb. Carinaria, Firola und Amphicora*; *Zeitschr. für wissenschaft. Zool.* iii., 1851, p. 228.

³ See *Zoologie de la Bonite*, p. 362.

poda.

of fossiliferous formations. Lamanon, the naturalist of La Peyrouse's unfortunate voyage, believed that he had discovered, in the *Atlanta*, the living type of the *Cornua Ammonis*; and the resemblance to the compressed and carinate species of *Ammonite* is undoubtedly very close; but it is one of analogy merely.

FAMILY II.—FIROLIDÆ, Woodward.

A small branchial shell or none.

Genus *CARINARIA*, Lam.—The next step in the departure from the common type of Univalves is made by the *Carinaria*.

Sp. *Carinaria cymbium*, L. (fig. 70).—In this species the somatal (fig. 70, A, B, C) far exceeds the visceral (D)

Fig. 70.
Carinaria Mediterranea.

division of the body, and the shell E is correspondingly reduced in size and adapted only to cover the visceral sac circumscribed by the free border of the mantle *h h*. Of the three divisions of the "soma," the cephalic A is the largest, the pedial B the least. The discoid portion *d'* of the foot is less distinctly separated from the pinniform part *d* than in *Atlanta*, and the tail C bears no opercule, the small shell being closely filled by the pallial and visceral mass, and affording no protection to the soma. The somatal integument is lined by a strong layer of decussating muscular bands, which layer is much more distinct and better developed than in other Heteropods; in the fin the muscular bands constitute four distinct layers: those of the two deeper-seated ones crossing the superficial layers obliquely. In the mid-space between the right and left layers lies the cellular tissue with the pedial vessels and nerves. The cephalic ganglions *u* are connected with the pedial ganglions *v* by commissural "cephalo-pedial" cords of a length corresponding with that of the cephalic division of the body, and consequently forming a so-called "œsophageal collar" of much greater extent than in *Atlanta*. Besides branches from this collar to the fin and tail, one is sent to the visceral ganglion *x*, and this brings the fin in relation with the branchial, circulating, and cephalic influences. The cephalic ganglions supply the same parts as in *Atlanta*, communicate with the small buccal ganglion, and send a nerve to the visceral ganglion *x*, situated at the base of the pallial division of the body.

The mouth is provided with a large rasping glottidium *a'* armed as in *Atlanta*; the œsophagus presents a fusiform dilatation *m*, in its course to the liver *p*; the intestiniform stomach *n* describes a curve in that organ; the intestine is re-

flected dorsad and forward to terminate (*o*) at the fore-part of the pallial division, a little to the right of the median plain. The salivary glands *f* form a pair of cæcal tubes, relatively shorter than in *Atlanta*. The liver *p*, of a violet colour, fills the hinder half of the shell. The branchiæ *i* are more constant and are relatively larger than in *Atlanta*; in the form of pinnate processes projecting from the fore-part of the shell-aperture. The heart is composed of an auricle and ventricle, the latter overlying the former, and giving origin to a large aorta *z*. The testis *w*, of a gray colour and granular texture, lies in the upper and back part of the visceral mass, sends off a sperm-duct, which dilates at its commencement into a nodular receptacle *y*, lodged on the substance of the liver, and then extends,

to terminate in the groove which leads along the right side of the animal, to the base of the penis *z*. This consists of two non-retractile appendages, hanging from a common base of attachment to the right side of the body; one of these is grooved lengthwise, and is the true intromittent part; the other has a granular structure within, and seems to be an excitatory organ.

The *Carinaria Mediterranea* of Lamarck (a synonym probably of *Car. cymbium*, Linn.) takes its name from the sea which it inhabits. The *Carinaria vitrea* is a native of the Indian ocean; its shell is highly prized.

In a closely allied genus, called *Cardiopoda* by D'Orbigny and *Carinaroides* by Eydoux and Souleyet, the shell is flexible, convolute, with the cartilaginous peristome expanded and bilobed in front, and enveloping the spire behind. The two figures above the part of cut 70, opposite the right hand, exemplify the shell, that on the opposite side is the shell of *Carinaria*.

Genus *FIROLA*, Péron and Les.—As amongst the land Gastropods the snails have a house-shell, the slugs a mere heart-shield, whilst in *Oncidium* and *Philomycus* even this rudiment of a shell disappears; so in the present sea Gastropods, so singularly modified for a free swimming or floating life in mid-ocean, while one genus has a shell developed to include the whole body, and another has it reduced to a mere protective covering of the heart and a few other viscera; a third genus, with scarcely any other organic modification of importance, shows no trace of shell.

These parallel conditions of variability in the testaceous appendage of the skin in different natural groups of the Molluscan class show plainly the low grade of that appendage in the scale of organic characters, and the relative standing of pure Conchology in Zoological science.

The genera *Firola* and *Firoloides* exhibit the zero phase of shell development in the Heteropodous group. The pallial or visceral division of the body presents its least proportion, the cephalic as contradistinguished from the pedial part, its greatest proportion. The foot is now a mere appendage to the somatal division, from which the cephalic part, properly so called, can no longer be distinguished as in *Atlanta*. The general form of the body, the transparency of the integument, and its muscular layer, are very similar

Gastero-
poda.

Gastero-
poda.

to those in *Carinaria*; but some species of *Firoloids* have no tentacles (fig. 71), and in none is the disc developed on the foot; this is exclusively a fin in form and function. The mouth (fig. 71, *a*), and mouth-mass *a b*, extend far in advance of the cephalic ganglions *u*, and eyes *c*. The commissural cords connecting those gan-

Lesueur³ first discovered the distinction of the sexes in the *Firoloids*. The testis (fig. 71, *u*), is a whitish granular body, situated at the upper and back part of the visceral mass. Its duct dilates into a receptacle (*w*) on quitting the gland, then contracts to a tube of capillary tenuity opening into the groove that is continued into the intromit-

Gastero-
poda.

Fig. 71.
Firoloides Lesueurii.

glions with the pedial ones *v*, cross the sides of the ingluvial dilatation of the gullet *m*, and form a very long cesophageal collar. The alimentary canal extends to near the caudal end of the body before it begins to make its molluscos inflection, and to expand into the gastro-biliary sac, with the substance of the liver *p*. The very short intestine *o* ascends, forming merely a right angle with the axis of the trunk before it terminates in a vent *o'*, just behind the renal sac and heart. From the ventricle a large aorta proceeds, and divides into a visceral and a somatal part; the latter advances forwards, sends off a small branch to the tail, a larger one to the foot, and is itself continued to the head. The pedial artery terminates abruptly in the reticulate venous sinus of the foot, and is said to exhibit a strong contractile power at its termination;¹ whence it is probable that, when the foot is in vigorous action as a swimming organ, the flow of blood into it is free; but when the muscles are at rest, the current may be decreased or checked. From the general transparency of the tissues of the *Firoloids* the delicate *membrana propria* of the wide and effused sinuses by which the venous blood is guided, and finally returned to the auricle, has been overlooked. That such an essential part of the mechanism of circulation should therefore be absent, and the blood-corpuscles be doomed to wander back to the heart "as best they may,"² is an inference characteristic of the school which repudiates final causes (or purposive adaptations) in organic structures.

From the delicacy of the somatal tissues it may well be supposed that the oxygenated sea-water re-acts upon the generally diffused venous blood; and it is certain that in *Firoloides* proper, as in some species of *Atlanta*, branchial filaments are not developed, and the ciliated subspirial band represents the sole localized or special breathing organ. The renal sac is contractile, and alternately receives and expels sea-water. Two small salivary caecal tubes communicate with the mouth.

tent and excitory appendage. This depends from the right hinder and lower angle of the body, and divides into two parts; the glandular portion terminating in a globular body. The ovary in *Firoloides*, as in *Firolo*, terminates the small visceral mass behind; it usually presents ova, with a well-marked germ-cell and nucleus. The albuminous sheath of the excluded eggs is frequently seen hanging from the outlet of the short oviduct like a filamentary appendage.⁴

The *Firoloids* are amongst the most abundant of the pelagic Mollusks; they float in myriads on the surface of the Mediterranean, and in the warmer zones of the Atlantic and Pacific Oceans.

In *Firolo* proper, the visceral mass, answering to the pallial division of the body in *Atlanta*, is situated, as in *Carinaria*, at about one-fourth from the hinder end of the somatal division. This end terminates in a filamentary appendage, varying in size and shape in different species.⁵ The branchial filaments, from twelve to fifteen in number, project from the slight border or fold of the small mantle, which leaves the upper and back part of the visceral mass exposed. The transparent integument of the body has a few coloured tubercles scattered over it. A rudiment of a disc has been seen on the compressed foot of some *Firolo*, but is not constant. A pair of small tentacles are present in some species, not in others; they appear, however, not to be constant in all the individuals of the same species. In fact, the determination of a species is by no means an easy or satisfactory operation in these soft, contractile, transparent Mollusks.

The *Firolo Keraudrenii* has a finely granular skin, and a long filamentary caudal appendage; it is about 2 inches in length.

In *Firoloides* the visceral mass is terminal; only the short filamentary appendage projects beyond it; in *Fir. Desmarestia*, and in *Fir. Lesueuria*, the appendage is multi-articulate, or antenniform. These delicate little Heteropods rarely exceed an inch in length; they occur in both the Pacific and Atlantic Oceans.

ORDER II.—TUBULIBRANCHIATA, Cuvier.

Branchiæ two, symmetrical, behind the heart; inclosed with the other soft parts of the animal in a long shelly tube.

Gen. *Dentalium*, Linn.

¹ Prof. Huxley, *Phil. Trans.*, 1852.

² *Journal of the Academy of Natural Sciences of Philadelphia*, vol. i., p. 3; *Firoloides* is dioecious, Huxley, *Phil. Trans.*, 1852.

³ The idea of the posterior termination of the body being homologous with part of the foot of gasteropods has been brought forward as a novel one by the author of the paper published in the *Philosophical Transactions* for 1853. But I concur in the justice of the following remarks by the distinguished naturalists of the *Voyage de la Bonite*:—"C'est la fausse analogie que l'on a ainsi établie entre de simples expansions de la peau et les véritables organes locomoteurs, qui à surtout fait méconnaître les rapports naturels de ces Mollusques." *Zoologie de la Bonite*, 8vo, 1841-1852, p. 346. The part *e* (fig. 71) may be homologous with the hind part of the body from which the hind lobe of the foot is developed in *Limax* and *Doris*, but not with that lobe itself.

⁴ *Ibid.*, p. 32.

⁵ *Zool. de la Bonite*, plate xvi., fig. 1.

Gastero-
poda.

ORDER III.—CYCLOBRANCHIATA, Cuvier.

Branchiæ usually a series of lamellæ, surrounding the body between the foot and mantle.

FAMILY I.—PATELLIDÆ, Woodward.

Shell with the apex turned forwards.

Genus PATELLA, Linn. (*Limpets*).—Head with two acuminate tentacles, ocelli sessile, on the outer side of their base. Pallial margin fringed; branchial series continuous. Shell covering the body, oval, with a subcentral apex.

The tongue of the common British limpet (*P. vulgata*) is rather longer than its shell; it has 160 rows of teeth, with 12 teeth in each row, or 1920 in all (Forbes).

The intestinal canal is very long and forms many convolutions, the rectum being reflected, so that the vent is placed under the head on the right side, whilst in *Chiton* it lies in the mid line at the posterior extremity of the body.

"The limpets live on rocky coasts, between tide-marks, and are consequently left dry twice every day; they adhere very firmly, by atmospheric pressure (15 lb. per square inch), and the difficulty of detaching them is increased by the form of the shell. On soft calcareous rocks, like the chalk off the coast of Thanet, they live in pits half an inch deep, probably formed by the carbonic acid disengaged in respiration; on hard limestones only the aged specimens are found to have worn the rock beneath, and the margin of their shell is often accommodated to the inequalities of the surrounding surface. These circumstances imply that the limpets return to the same spot to roost. On the coast of Northumberland we have seen them sheltering themselves in the crevices of rocks, whose broad surfaces, overgrown with nullipores, were covered with irregular tracks, apparently rasped by the limpets in their nocturnal excursions." (Woodward.)

The limpet is much used by fishermen for bait; on the coast of Berwickshire nearly 12,000,000 have been collected yearly, until their numbers are so decreased that collecting them has become tedious (Dr Johnston). In the north of Ireland they are used for human food, especially in seasons of scarcity; many tons weight are collected annually near the town of Larne alone (Pattison).

On the western coast of South America there is a limpet which attains the diameter of a foot, and is used by the natives as a basin (Cuming).

(For the anatomy of the limpet see Cuvier, *Mém. sur les Mollusq.*, No. 18, pp. 15–19, pl. ii., figs. 8–19, and the fig. of *Patella algira*, Desh. in Cuv. *R. Ani.*, éd. ill., *Moll.*, pl. 66.)

FAMILY II.—CHITONIDÆ.

Shell subdivided into eight pieces.

These pieces or valves form an imbricate series on the middle of the back (fig. 72, *a*). Each has a more or less wide plate of insertion sunk into the mantle, with a deep lateral notch on each side: the anterior and posterior valves

Fig. 72.
Chiton squamosus.

Fig. 73.
Chiton.

often with other notches on the terminal edges. The first

seven plates have posterior apices (fig. 73, 1–7), the eighth has its apex nearly in front. The six middle plates are each divided into a dorsal and two lateral areas. Gills conic, lamellar, in two series, one on each side the hinder part of the body. The heart is elongated like a dorsal vessel. Mantle not covered by shell at the circumference, with the margins hard, coriaceous, often aculeate or squamose. Ventral disc elongate, narrower than the body (fig. 72, *b*). Eyes and tentacles none; head crested by a wavy veil. The combined genital organs are symmetrically repeated on each side, and have two orifices.

More than 200 species of Chitons are known; they occur in all climates throughout the world; are most abundant on rocks at low water, but frequently obtained by dredging in 10–25 fathoms water. Some of the small British species range as deep as 100 fathoms (Forbes.)

The species of this genus are very numerous and difficult to distinguish otherwise than by accurate measurements of the comparative length and breadth, the greater or lesser inequality, &c., of the pieces of shell, and by the nature of the margins of the mantle which are not covered by the dorsal shields. In some species these margins of the mantle cover, as though they came together by continued growth, the dorsal shields, so that the shell is concealed within them. Of these Middendorff¹ forms the sub-genus *Cryptochiton* (Sp. *Cryptochiton Stelleri*, Middend., l. i. Taf. i., figs. 1, 2, *Chiton amiculatus*, Sowerby, *Conchol. Illustrations*, *Chitones*, fig. 80, Reeve, *Conchologia system.* ii., Pl. 132, 133, fig. 80; from which *Chiton amiculatus*, Pall., according to Middend., does not differ). The remaining species form the sub-genus *Phanochiton*, Middend., in which the branchiæ are sometimes situated backwards, and the row of pieces of shell is interrupted by the mantle (*Dichachiton*, Middend., *Chitonellus*, Lam., Sp. *Chitonellus laevis*, Lam., Blainv. *Malac.*, pl. 87, fig. 5); or the pieces of shell close upon one another, and the branchiæ are placed round about at the sides of the mantle (*Hamachiton*, Middend.) To this last division belong most of the species of the genus *Chiton* of Lamarck.

Dr Gray has called attention to the value and constancy of the modifications observable in the inserted part of the plates, and this experienced naturalist remarks:—

"It has been objected that the character derived from the form of the plate of insertion of the valves can only be seen by the destruction of the specimens as they are usually kept in cabinets; but they can generally be seen from the under side, or through the substance of the mantle. When this is not the case, the form of the plate of insertion can be easily developed by paring away the under surface of the mantle, so as to show part of the edge of the valves, without injury to the specimen; and they may be easily made more visible through the inner side of the mantle by being soaked for a few hours in a weak solution of caustic potash; but care should be taken that the specimen is not left too long in soak, nor the solution be too strong, otherwise the margin will be dissolved.

"The form of the plate of insertion may also be easily predicted by inspecting the inner surface of the valves, for the notches in the margin leave an impressed line from the vertex of the valve, as they are gradually filled up by the growth of the valve.

"The valves are best separated from the coriaceous skin of the body, called the mantle, by soaking them in a strong solution of caustic potash; as then the plates of insertion are cleaned, and not broken, which they are likely to be if they are taken by force from the mantle.

"The number of notches in the plates of insertion is sometimes, but very rarely, liable to variation. In one specimen of *Chiton Bowenii* in the Museum Collection, the plate of

Gastero-
poda.

Gastero-

poda.

insertion of the last valve but one has two notches on one side, but the normal single notch of the genus on the other."

The anatomy of the *Chiton* has been illustrated in the great work of Poli, *Testacea utr. Siciliae i. Multivalv.*, pp. 1-10, tab. iii.; by Cuvier, *Mém. pour servir à l'Hist. nat. et à l'Anat. des Mollusques*, No. 18, pp. 22-28, pl. iii., figs. 8-14; and, more recently, in an exhaustive manner, by A. Th. Middendorf, *Beschreibung u. Anatomie neuer Chitonen*, *Mém. de l'Acad. impér. des Sc. de St Pétersbourg*, 6e série, tom. vi., 1848, pp. 67-215, av. 14 pl.

The chief peculiarities of organization have been strikingly summed up, with perhaps some overstraining of the similes, by Dr T. Williams, as follows:—

"A *Chiton* has a carapace like an isopod Crustacean, a dorsal vessel like an Annelid, bilateral symmetrical reproductive viscera like an acephalous Mollusk, a head and foot like a patelloid Gastropod, a posterior anus like the *Fissurellidae*, and branchiae like those of the brachyurous Crustacea! Such manifold affinities at once unite and sever this odd group from several most dissimilar classes." (Dr T. Williams, *Ann. & Mag. Nat. Hist.*, xvi., 408, 1855.)

The fry of the *Chiton* are not provided with a deciduous shell: they swim by a cincture of long vibratile cilia, near a constriction which divides the oval embryo into two subequal parts; a tuft of filaments and two dark eyespecks denote the head. The hinder half elongates, becomes marked on the back with seven transverse furrows, between which the first rudiments of the shell-plates appear as granules of carbonate of lime in the integument, which coalesce into narrow bands or bars, with an irregular wavy outline: they increase by the addition of layers on the under surface: and their development gives no countenance to the idea that the hindmost valve is the homologue of the univalve shell of the limpet, and the seven in front supplementary pieces. Lovén, who has described the development of the *Chiton*, regards the girdle of cilia as answering to those on the velum of other Gastropods; the homology of the head of the embryo, with its tuft of filaments, to the prominence supporting the flagellum in some embryo bivalves (fig. 27), is more doubtful.

ORDER IV.—SCUTIBRANCHIATA, Cuvier.

Branchiae plumose or pectinate, and, with the entire body, protected by a widely-open shield-shaped inoperculate shell. Heart with two auricles, and traversed by the rectum.

FAMILY I.—HALIOTIDÆ.

(Ear-shells.)

Head with two long and slender tentacles; eyes on short pedicles at the outer side of their base; proboscis short; branchial cavity with a fold or siphon occupying the slit or perforation of the shell; retractor muscle large, subcentral.

Fig. 74.
Haliotis tuberculata.

Genus HALIOTIS, Lam. (*Ormers* or *Ear-shells*).—Shell ear-shaped, with a spiral ridge on the left side, and a series of holes over the pallial fissure. These holes are closed as

the animal grows from near the apex of the shell onwards, new ones being formed near the aperture, where the notch becomes changed into a hole. The foot (fig. 74) *dd* is expanded and sub-circular, its side lobes support a double row of cirri and crenate processes; cirri project through the perforations of the shell *i, i*.

Haliotis tuberculata (fig. 74) abounds in the Channel Islands, where it is used for food; the hard tissue of the muscular foot, *dd*, and retractor being pounded before the animal is cooked.

Species of *Haliotis* range from Kamtschatka to New Zealand. In the latter island is a sub-genus (*Padollus*), in which the multi-perforate shell has two parallel spiral ridges.

The lining nacre of the ear-shell is beautifully iridescent; most richly so in *Haliotis iris* and *Haliotis gigas*, which latter shells are imported in vast numbers for that substance.

Genus JANTHINA, Lam. (fig. 75).—Head with a large ventricose proboscis *a*; two subulate tentacles *b*, with short eye-stalks *d* at their base; foot *f* small, with lateral folds

Fig. 75.
Janthina fragilis.

g continuous behind. It secretes (in the female?) a series of albuminous air-vesicles *i*, constituting a floating raft, to the under surface of which the ovi-capsules *mm* are attached. M. Rang states that this float is cast adrift after the egg-bags are attached. The shell *n* of the *Janthinæ* is like that of a land-snail, and commonly of a beautiful purple colour; it is ventricose, thin, and sub-pellucid, with the aperture triangular, and the columella straight and produced beyond the margin of aperture. Myriads of these beautiful and delicate oceanic snails float in the Mediterranean, Atlantic, and Indian Oceans; specimens are occasionally drifted to the S.W. coasts of England. They are said to feed on the small floating *Velella*. The anatomy of *Janthina* has been given by Cuvier in the *Ann. du Mus.* xi., pp. 121-130; and in the *Mollusques*, *Mém.* 15, pp. 2-10, figs. 1-8.

FAMILY II.—FISSURELLIDÆ, Woodward.

Head with a short proboscis; with two subulate tentacles, having sub-pedunculate eyes on the outside of their base. Mantle with a siphonal aperture in the back, and containing two symmetrical pectinate gills. Foot expanded, with a series of short cirri above its sides. Shell symmetrical, but with a spiral nucleus, which is covered in most by later growths of the shell; the apex perforated corresponding to the branchial opening.

Genus FISSURELLA, Lam. (*Key-hole Limpets*).—Shell oval, conical, radiately ribbed; apex subanterior or central; perforation oblong, subapical; aperture wide, oblong; cavity simple, muscular, impression with the points incurved. The shell of the young animal is subspiral, with a perforation in front of the apex. If the branchial excretory fissure were extended so as to bisect the shell, and the two symmetrical halves were connected by a hinge and adductor muscles, the *Fissurella*, with its symmetrical pair of gills, would closely resemble a Lamellibranch, with a head and a very large and broad foot.

In *Emarginula*, Lam., the vent is anterior, and the shell presents a slit at its front margin; the foot supports a single cirrus on its back part. In some species of *Emarginula* the

Gastero-

poda.

Gastropoda. shell can be partially covered by the mantle. The young of *Emarginula fissura* have a very minute, recurved, spiral shell, with rapidly enlarging and finely striated whirls without any slit. (Lovén.)

above described; *ll* the simple elongated salivary follicles; *m* the oesophagus girt by the nervous collar before its ex-

Gastropoda.

ORDER V.—PECTINIBRANCHIATA, Cuvier.

Branchiæ composed of plates so formed and united as to resemble a comb, usually two in number, very rarely obsolete; contained in a dorsal pallial cavity opening widely above the head. This order of dicecious Gastropods is the most numerous in genera and species; it includes nearly the whole of the spiral Univalves, and also many with shells simply conical. All the Pectinibranchiata have two tentacles and two eyes, in many supported upon pedicles; the mouth is produced into a proboscis; the males have the intromittent organ attached to the right side of the neck, and, in most, it is folded back within the pallial cavity, but in *Paludina* is retracted into a prepuce opening at the right tentacle. The female has a nidamental gland excreting the albuminous matter of the nidus for the eggs, which is often large and complex. In some Pectinibranchs the branchial aperture is entire; in others a portion of it is fissured or produced into a siphon; the mouth of the shell presents conformable modifications: in some the shell is without an operculum, but most Pectinibranchs possess one. In the selection, compelled by the limits of the present article, the chief modifications of the soft parts or "animal" of the univalve shells will be illustrated.

Section 1.—ASIPHONATA.

FAMILY I.—CALYPREIDÆ, Woodward.

(Bonnet and Slipper Limpets.)

Head with two tentacles, having small sessile eyes on the outside of their base; branchia single and long; sides of the body in front of the foot more or less expanded and produced; tooth-strap elongate; teeth 3-1-3; the central simple, recurved, toothed at the tip; the inner lateral broad, with a triangular toothed tip; the outer lateral tooth claw-like; the second lateral minutely toothed at the end. The eggs are inclosed in a thin membranous bag in small groups under or in front of the foot of the animal. The shell in the egg is subglobular, of one or two gradually enlarging whirls, which rapidly enlarge as soon as the animal is hatched. Shell limpet-shaped, but with the apex more or less spiral, and with a variously-shaped calcareous process from the inner surface to which the retractor muscle is attached.

Genus CALYPTRÆA, Lam.—Head with a short and broad muzzle (fig. 77, *a*), truncate, and with the angles slightly produced; tentacles *b* rather short; aliform expansions *d* from the sides of the neck (in *Calypeopsis*). Shell with the inner process half-cup-shaped (*Calyptræa*), or cup-shaped (*Calypeopsis*) (fig. 76, *b*), or with a second calcareous plate formed by the surface of the foot, and adherent to the foreign base of attachment (*Lithedaphus*). The anatomy of a male *Calyptræa Byronensis* is shown in fig. 77. *a* is the mouth, *k* the glottidium with the tongue-strap and teeth as

Fig. 76.
Calyptræa Byronensis.

Fig. 77.
Calyptræa Byronensis.

pansion into the stomach *n*; this cavity is almost concealed by the liver, in the substance of which the intestine makes an abrupt bend upon itself and returns, crossing the dorsal side of the stomach to terminate in the right side at *p*, close to the branchial or pallial aperture *h*. The pallial cavity is laid open and spread out to show the extent of the single comb-shaped gill *ii*. The great branchial vein *x* enters the auricle *w*, and the small, dark, muscular ventricle propels the blood through a short bifurcating aorta. The testis *r* sends its product by the duct *d* to the base of a long and slender grooved intromittent organ *c*, projecting from the right side of the head. *ff* shows the smooth convex mass, chiefly muscular, which fills the "cup" (fig. 76, *b*); the dark colour indicates the shape and position of the insertion of the adductor muscle. These singular "cup-and-saucer" limpets adhere to rocks or shells, to the inequalities of which the margin of the "saucer" adapts itself, indicative of their sedentary habits. *Lithedaphus* is a fixture.

In one group the shell is elongated, and the inner process is a partition covering the hinder half of the cavity like a slipper, whence the name *Crepidula* (little slipper) given to this group or genus.

The shells of all the *Calyptræidæ* are peculiar for their great range of adaptive modifications, which have given rise to many nominal species. The experienced naturalist Dr Gray remarks:—

"*Crepidula fornicata* varies in shape according to the body on which it rests; four or five different ages are frequently found riding upon each other. When growing on *Pecten concentricus* it is found to have ribs corresponding to those of the *Pecten*. When found in the cavities of shells it is white and flat, with a convex diaphragm; the younger specimens are rounded, but generally become elongated by age; and it is otherwise very variable in shape, conforming itself to the position it occupies in the throat of the shell. When found among stones at the roots of seaweed, it is generally of a small size, with a convex diaphragm.

"*Crepidula dilatata* changes its form and character according to the body to which it happens to be fixed:—

"1. If attached to a broad stone or other body, the shell is smooth, circular or ovate, and moderately convex; it is then *C. dilatata*, *C. peruviana*, *C. depressa*, *C. patula*, *C. lineolata*, *C. Adolphæi*, *C. chilensis*, and *C. strigata*.

"2. On the contrary, if fixed to a small round stone, and

Gastropoda.

the shells are obliged to group themselves on one another, it is then narrow, very convex, and *C. nautiloides*.

"3. When the young shell happens to be in deeper water, and fixes itself between the roots of sea plants, it becomes irregular, thick, and of a uniform colour; it is then *C. pallida*.

"4. If it happens to be fixed on the inside of a dead spiral shell, especially if that shell is inhabited by a soldier crab, it becomes flat or even concave externally, and is of a white colour; it is then *C. plana* or *C. unguiformis*.

"*Crepidula patagonica* and *C. aculeata* occur attached to stones on the coast of South America; the former often chooses situations much beaten by the waves.

"*Crepidula dilatata* forms large rounded massive groups, the lower shell being attached to a stone or shell, and the others all placed on the back of it."¹

FAMILY II.—TURBINIDÆ, Woodward.

In this family, as in the *Bullidæ*, the head and sides of the foot bear lobes, but they are fringed and tentaculate, as in *Haliotis*; the eyes are pedunculate outside the base of the tentacles. The gill-comb is single; the tongue-strap is very long, extending into the visceral cavity. Like the limpets, the Gastropods of the present family feed on seaweeds; they include the fabricators of the top-shells (*Turbo* and *Trochus*) and pheasant-shells (*Phasianella*) of the Conchologists; nearly all of which have a brilliant nacreous lining. The operculum is either shelly, or is horny and multispiral. The *Trochus conchyliophorus*, Born., Gm. (Cuv. *Règne Animal*, éd. ill., *Moll.*, pl. 41, fig. 3), causes little stones and pieces of bivalves from the bottom on which it creeps to adhere to its shell; these foreign bodies in time grow to the shell, which thus acquires a very irregular appearance. Lamarck confounded with this species, from the West Indian Seas, a fossil species from the tertiary formations, which presents the same peculiarity, under the name of *Trochus agglutinans*. The anatomy of the *Trochus* is given by Cuvier, in *Ann. du Mus.* xi., pp. 184, 185; *Mollusques Mém.* 16, pp. 15, 16, fig. 13.

FAMILY III.—PALUDINIDÆ, Woodward.

The Gastropods of this family inhabit fresh waters, and have a world-wide distribution. Our well known river-snail (*Paludina vivipara*, Lam.) may be regarded as the type; the females are full of young in spring. The ova are hatched in a long and wide oviduct, and the young escape with shells, the periostracum of which bears spiral rows of cirri. The shell of the adult is smooth, of a dull-green colour, with red-brown bands and very convex wreaths. The right tentacle is perforated in the male individuals with an aperture which gives passage to the penis. The gills consist of three series of filaments. It is found in rivers, canals, and other fresh waters; in the mud, or hiding under stones; also creeping under water-plants. The anatomy of the *Paludina vivipara*, Lam., is given by Swammerdam, *Bibl. Nat.* i., pp. 169–180, tab. ix., figs. 15–18; by Cuvier, *Ann. du Mus.* xi., p. 170, *Mollusques Mémoire* 15; and it has recently been admirably completed by Leydig, *Ueber Paludina vivipara, ein Beitrag zur nähern Kenntniss dieses Thieres in embryologischer, anatomischer und histologischer Beziehung*, in Siebold u. Kölliker's *Zeitsch. f. wissensch. Zoologie*, bd. ii., 1850, pp. 125–197, pls. xi., xii., xiii.

FAMILY IV.—LITORINIDÆ, Woodward.

Head probosciform (fig. 78, *a*); tentacles *b* subulate, with the eyes sessile on the outside of their base; foot of

moderate size, with a linear duplication in front, and a groove along the repent surface; gill single; mantle with a rudimentary siphonal canal. Shell spiral, turbinated, or depressed; aperture entire; operculum horny.

Genus LITORINA, Férussac (*Periwinkles*).—Shell turbinated, thick, with few whorls, and no nacreous lining; operculum paucispiral.

Sp. *Litorina litorea* (Common Periwinkle).—This well-known univalve lives in the lowest zones of sea-weed between the tide-marks; it is oviparous, and is used for food.

Litorina rudis.—This species is viviparous, and as the young acquire a calcareous shell before exclusion, it is not eaten; it frequents a higher zone than the common periwinkle. The sides of the grooved foot advance alternately in progression.

Genus SOLARIUM, Lam. (*Stair-case Shell*).—To a subgenus of this group (*Torinia*, Gray) belongs the Mollusk with the spiral turritiform operculum, fig. 56.

Genus PHORUS, Montfort (*Carrier-Shell*).—The propriety of separating the "carrier-shells" from the *Trochi*, which they resemble in shape, has been proved by the discovery of two living species, in both of which the soft parts are distinct from those of *Trochus* proper. Except in that the eyes are not raised on pedicles, the outward form of the animal is similar to that of *Strombus*, which *Phorus* resembles also in its mode of progression, but its true affinities are with the *Litorinidæ*.

The animal of *Phorus* (fig. 78) is very slender in pro-

Fig. 78.
Phorus exutus.

portion to the size of the aperture of the shell. The foot is divided into two parts, of which the anterior one *d* is expanded, subservient to the purposes of locomotion, and the hinder one supports a large horny operculum *f*, which is partially free, as in *Solarium*. The proboscis *a* is very prominently developed and annulate; and the tentacles *b* are long and tapering, with the eyes *c* sessile on the outside of their base. The portion of the mantle lining the aperture of the shell is vascular, thin, and delicate, extending over the front and outer lip, which is often much produced and uneven in outline, especially in *Phorus exutus* (fig. 78).

"The *Phori* invariably inhabit rough places incapable of accommodating a gliding motion, and their mode of progression, like that of the *Strombi*, is by little jumps. Each species has its own peculiar manner of collecting the debris of shells or pebbles which cover the ground it inhabits, and each has, to a certain extent, its peculiar kind of debris." (Adams.)

In *Phorus Solaroides*, Adams, the animal is character-

¹ *Guide to the Systematic Distribution of the Mollusca in the British Museum*, 8vo, 1857, p. 117.

Gastero-
poda.

ized by numerous circular striæ, the tentacles are laterally compressed and rather prismatic, the proboscis is long and transversely wrinkled, yellow at the tip and on the under surface, but pink between the tentacles, which are straight, rigid, and opaque dead-white; the eyes are black and conspicuous. Hab. China Sea.

As compared with the *Calyptræidæ* the carrier-shell have a divided *Stromb*-like operculated foot, are of active habits, and produce a regular convoluted shell, whilst the cup-and-saucer shells have a simple foot, live attached to foreign bodies, seem rarely to perform the act of progression, have no operculum, unless the rare secretion of a calcareous plate to the place of attachment can be regarded as the homologue of one, and the spiral type is not carried out in the completion of the adult shell.

FAMILY V.—TURRITELLIDÆ, Woodward.

Head with a short proboscis; eyes sunk in the outside of the base of the tentacles; margin of the mantle fringed; foot short; branchia single. Shell tubular or spiral, apex partitioned off; aperture circular, entire; operculum horny multispiral. To this family belong the "turret-shells" (*Turritella*, Lam.), the "worm-shells" (*Vermetus* and *Magilus*), and the wentle-traps (*Scalaria*, Lam.), of which the once rare and highly-prized *Scalaria pretiosa* is a beautiful example. The wentle-traps exude a purple fluid when molested.

In the *Vermetus* of Adanson (the *Serpula lumbricalis* of Linnæus) the tubular shell is thin, divided by partitions, with the spire adhering at the apex; elsewhere it is loose. The aperture is orbicular, with the margins connected. The head supports two tentacles, which are oculiferous externally at the base. The posterior appendage of the body is bent downwards, and is mostly furnished with an operculum. The branchiæ are arranged in a conical series, at the left side of the respiratory cavity.

The peculiar solidification of the elongated shell of the adult *Magilus* has already been mentioned. In both the above genera of tube or worm shells the shell has the form of a regular spiral univalve when the animal is young. *Magilus* inhabits madreporic masses in the Red Sea; by its anatomy it is nearly allied to the whelk family (*Buccinidæ*).

FAMILY VI.—CERITHIADÆ, Woodward.

Head with a short non-retractile muzzle; tentacles with the eyes at their apex (fig. 79), or supporting them on short peduncles; margin of the mantle with a rudimentary siphonal fold. Shell spiral, elongate, and many-whirled; aperture oval, oblique, with a short truncate or recurved canal in front; operculum horny and spiral. About 100 living species of *Cerithium* are known; they have a world-wide distribution, but flourish best in the tropics. They live in great part in the sea, partly in brackish water or at the mouths of rivers. The fossil species, which are still most numerous (upwards of 400 have been defined), are almost all limited to the Tertiary formations. Amongst these *Cerithium giganteum* deserves to be noticed, a species found in France near Grignon.

The animal of *Cerithium obtusum*, Lam. (fig. 79), captured by Mr Adams at the

mouths of rivers in Borneo, "has a broad, suborbicular, and expanded foot, and an elongated, subcylindrical annulated trunk of a light brown colour, with three rather broad,

Fig. 79.

Cerithium obtusum.

with three rather broad,

well-defined, opaque, yellow lines extending along its upper surface, the central one of which extends from the head to very near the extremity of the proboscis, where it is bifid, the two forks diverging; the two lateral lines are shorter, not bifid at their extremities, and reach forward on the head to within a little distance of the origin of the tentacles; the tentacles are very short, annulated, with the eyes (which are small, though with a distinct iris and pupil) situated at their tip, whereas they are mostly placed on tubercles situated on the outer side of the base of the tentacles, or on the tentacles themselves at a little distance from their origin. The foot is of a light pinky brown on its upper surface, mottled with a deep rich brown, and on the under surface is lilac."

The *Cerithia obtusa* live in brackish water in mangrove-swamps and the mouths of rivers in Singapore and Borneo. Sometimes they crawl on the stones and leaves in the neighbourhood, and are not unfrequently found suspended by glutinous threads to boughs and the roots of the mangroves. The operculum is round, horny, with a central nucleus and concentric elements; it is semitransparent, and borne upon the posterior part of the foot at its extreme end. When the animal hibernates it retracts itself into the shell, and brings its operculum to fit closely into the aperture, after having previously affixed sixty or seventy glassy, transparent, glutinous threads to the place of attachment, when they occupy the outer or right lip, and extend half-way round the operculum.

"A species of *Cyclostoma* (*Megalomastoma suspensum*, Guilding) was found by the Rev. Lansdowne Guilding at the Island of St Vincent, suspended in like manner from the trees; and *Rissoa parva* has been observed by Mr Gray, upon our own shores (*Pro. Zool. Soc.* 1833, p. 116), to have the power of emitting a glutinous thread by which it attaches itself to floating sea-weeds.

"There is a very handsome *Cerithium* closely allied to the foregoing, which I have frequently found crawling languidly on the leaves of the *Pontedera* and sedges in the fluviatile marshes on the banks of the rivers in many parts of Borneo, and many miles in the interior where the water is perfectly fresh, and which has the eyes likewise terminal and the proboscis marked with crimson and yellow; the foot is very dark brown, and has a vivid scarlet line extending round the lower margin. The position of the eye varies considerably in this group. In an amphibious Bornean species, allied to *C. decollatum*, they are terminal at the end of peduncles; in other words, the tentacles are connate with the eye-peduncles for the whole of their extent. In *C. microptera* the tentacles extend a third beyond the eye-peduncles; in *C. decollatum* the eye-peduncles are truncated, with the eyes at the end, while the tentacle extends beyond them in the form of a minute filament; all these species have circular multispiral opercula."¹

The foregoing evidence of the living habits of the *Cerithia* has much interest in relation to the tertiary extinct species.

FAMILY VII.—PYRAMIDELLIDÆ, Woodward.

Head with broad ear-shaped tentacles, often connate, with the eyes at their base; proboscis retractile; foot truncate anteriorly. Shell spiral, turreted; aperture small; columella with one or more prominent plaits; operculum horny, imbricated.

Genus EULIMA, Risso.—"The head of *Eulima* is small, with the tentacles subulate and close together at the base, where they are rather swollen. The eyes are situated at the back of the head, behind the tentacles. The foot is rather expanded, especially at the sides, and is furnished with an ovate subspiral operculum. The polish of the shell is occasioned by the front edge of the mantle being

Gastero-
poda.

¹ *Zoology of the Samarang*, p. 43.

Gastero-
poda.

extended over it; the lobes are, however, difficult to observe, in consequence of the extreme timidity of the animal in speedily retracting them when disturbed. The soft parts of *Eulima major* are, like the shell, of an opaque pearly white, except that the tentacles are delicately tinged with orange in the middle and with yellow at the tip. The eyes, which are black, are usually concealed beneath the front of the shell, the tentacles only protruding. The foot is in advance of the head when the animal is creeping.

Genus STYLINA, Fleming (*Stylifer*, Brod.)

Sp. *Stylina astericola*.—This little Gastropod is remarkable for its parasitic habits, being commonly found immersed in the body of living star-fishes, or attached to the spines of sea-urchins. The mantle is thick and reflected over the body-whirl of the shell. The foot is much produced beyond the head, but is very little extended behind.

FAMILY VIII.—NATICIDÆ, Woodward.

Animal with a long retractile proboscis; tentacles often connate with an expansion of the head; foot large; mantle-lobes reflected over more or less of the shell; this is globular and with few whirls. Spire short and obtuse; aperture semilunar.

Genus NATICA, Lam.—The *Natica melanostoma* (fig. 80) is furnished with a strong coriaceous foot *d*, well de-

Fig. 80.
Natica melanostoma.

veloped in front, where it forms a fold *a*, which can be reflected back upon the head. By means of this the animal perforates the sand, while its tentacles are protected; but when the tide rises and covers the sands, the large side lobes and dilated hind part of the foot are expanded, and the *Natica* flaps along above the sand. A great peculiarity in the animal of this family is the existence of an operculigerous lobe *h*, which in the polished species nearly covers the shell, and is seen in our figure mounting up behind and partly covering the sides. In *Sigaretus* this lobe is extended entirely across, and covers the shell, while the operculum is rudimentary; in *Lamellaria* it not only incloses the shell, but extends beyond it in front.

Section 2.—SIPHONOSTOMATA, Cuvier.

Margin of the mantle prolonged into a siphon, by which water is conveyed into the branchial chamber. Shell spiral; aperture notched or produced into a canal in front; operculum horny, lamellar, rarely wanting. Most of this section are carnivorous.

FAMILY I.—CYPRÆIDÆ. (Cowries.)

Head with a proboscis (fig. 48, *a*), two long subulate tentacles *b*, with the eyes *c* usually at some distance from the base; foot *d* long and broad, truncate in front; mantle with side-lobes which can be reflected over the shell. These lobes, in most species, are beset with tentacles, often branched. The shell is richly enamelled by the secretion of the pallial lobes. It is convolute, with the spire concealed in the adult; the aperture narrow, enamelled at

each end; the outer lip, in the adult, thickened and inflected; often transversely crenate; no operculum. In the young of *Cypræa* the shell has a thin and sharp outer lip, a short but conspicuous spire, and a thin periostracum; the spire becomes concealed by the subsequent enamel deposits from the reflected mantle-lobes; the line along which these meet at the back of the skull is usually indicated by a pale line on the shell.

Sp. *Cypræa tigris* (Tiger Cowry) (fig. 48).

Sp. *Cypræa moneta* (Money Cowry).—Of this little shell many tons' weight are annually imported into England, for the purpose of barter with the negroes of the west coast of Africa.

Genus OVULUM, Brug.—This group of cowries has been separated from *Cypræa* proper on some characters of the shell which are barely of sub-generic value. In the *Ovulum volva*, or "weaver's shuttle shell," the mantle is furnished near the edge with a row of dark tubercles. A living specimen was taken by Mr Adams from a rocky coral bottom off the Island of Basilan, in the Mindoro Sea. It was languid in its movements, with the foot narrow, and folded longitudinally upon the slender coral branches along which it slowly glided.

The *Ovulum verrucosum* (fig. 81) approaches nearer to the type of *Cypræa*, having the mantle *h* partially lobed on each side; but it does not wholly cover the shell. The foot *dd* is flat and expanded; it is spotted black, on a white groundlike the mantle. The tentacles *b* are subulate, of a pure white, with black extremities; the eyes are on the outer side of their base. The longest slope and narrowest end is the fore-part of the shell.

Fig. 81.
Ovulum verrucosum.

This species is a sluggish, slow-moving Mollusk, not more sensible to alarm than the true cowries.

The specimen figured was captured at Mindoro, one of the Philippine Islands, on a sandy bottom, by Mr Adams.

FAMILY II.—VOLUTIDÆ, Woodward.

Head with tentacles supporting eyes near their base; foot very large, partly covering the shell when out of water; mantle in some genera reflected upon the shell; siphon recurved. The shell turretted or convolute; aperture notched in front; columella obliquely plaited; no operculum.

Genus MARGINELLA.—In this genus, as in *Cypræa*, the outer lip of the shell becomes thickened at the border (fig. 82), the spire becomes nearly or quite concealed, and the outer surface is enamelled.

Sp. *Marginella undulata*, Deshayes (fig. 82).—This species was taken alive by Mr Adams from a sandy bottom in the east coast of Africa. The proboscis *a*, tentacles *b*, the siphon, the foot *d*, and the mantle, are mottled with carmine on a yellowish ground, the border of the mantle bearing large crimson spots.

In the *Marginella diadochus*, Ad., the tentacles are yellowish with a row of marble crimsoned spots, the eyes black and minute, the mantle pale, semi-transparent, of a pinkish yellow, with a row of semioval crimson spots round the thin free edge, the remainder being covered with radiating linear spots and short waved lines of a crimson colour; siphon marbled with crimson; foot of a delicate yellowish-pink, marked with deep crimson rays. The shell is of a bright olive carnelian hue, conspicuously encircled at irregular intervals with broad black lines, having almost the

Gastero-
poda.

Gastero-
poda.

consistency of bands. This species was captured in the Straits of Sunda, from a sandy bottom, at a depth of about three fathoms.

The tentacles of the *Marginellæ* appear to vary in dif-

Fig. 82.

Marginella undulata.

ferent species. In those observed by M. Deshayes on the shores of the Mediterranean the tentacles are described as being short, whilst in this and the preceding species they are slender and elongated. The eyes of the *Marginella diadochus* are more pedunculated than those of *M. undulata* (Adams).

Genus VOLUTA, Linn., Lam.—In this genus the siphon has a lobe on each side near the base; the shell is ventricose, thick, with a short spire, having a mammillated apex. The aperture is large, deeply notched in front; columella plaited.

A beautiful species (*Voluta abyssicola*) was discovered by Mr Adams at the Cape of Good Hope.

"This elaborately carved species is one of considerable interest in a geological point of view, from the circumstance of its being the first living representative yet discovered of a group of highly sculptured Volutes abounding in the Eocene portion of the Tertiary beds of the British Isles. The principal of these, *V. lima*, *elevata*, *crenulata*, and *digitalina*, were distinguished by Mr Swainson as a sub-genus, under the name *Volutilithes*. The *Voluta abyssicola* is not identical in species with the fossils, being characterized by a closer and more sharply-defined pattern of lattice-work, which comprises as many as thirty transverse, and forty longitudinal ridges in a whirl. The upper edge of the whorls is depressly flattened at the sutures, forming a narrow ascending canal. The ridges are slightly nodulous at the point of crossing, and round the upper extremity impart a coronated aspect to the shell. The columellar plaits, four in number, are sharp and delicate. The outer lip is thin, and does not appear to be mature. The only specimen collected was dredged from a bank of dead shells and rounded iron-stones, at the depth of 132 fathoms." (Adams.)

Genus MITRA, Lam. (*Mitre Shells*).—The animal of *Mitra* has in general a very short foot, straight and continuous from side to side in some species, but in others notched and produced, with a thickened anterior margin. It is commonly narrow and rounded, or acuminate posteriorly, and it bears a very small semi-transparent horny

operculum, in some instances scarcely visible. The siphon is mostly directed forwards, and the somewhat short tapering tentacles have the eyes either situated about half-way, or they are placed on the outer side of the base. The head is long and very flat, and the tentacles are very close together at their bases. The proboscis is rarely exerted when they are crawling and lively, but as they become languid after capture it becomes distended with water and protrudes considerably. The animal of *Mitra flammigera*, one of the deep-water species, is very prettily marked. The body is gray, varied with round, well-defined white spots, and dark-brown blotches, of a pyramidal form, arranged in a row round the lower edge in a Vandyke pattern, and below that a white rim with a row of small, linear, horizontal black spots; the head is white, marbled with gray-brown; the eyes black, and the tentacles white, with a large oval black spot in their middle; the siphon is brown, edged with black, and with a broad white band at its free extremity. The operculum is very minute, horny, and transparent. Hab. Caramata Passage; 14 fathoms, hard muddy bottom, mixed with sand and broken shells.

Another species, with the same habits, the *Mitra interlirata*, is semiopaque, white, faintly mottled with light brown, with the eyes at the outer base of the tentacles, and

black. Hab. China Sea; 10 fathoms.

"The animal of that division of the genus which Swainson included under *Conohelix* is the same as in the typical species. I have found the *Mitra conus* buried rather deep in the soft black mud under the roots of trees in mangrove swamps, above high-water mark, in the Island of Basilan. The *M. conica* is found in company with other species of mitres, crawling slowly over the sandy mud in shallow places, among the islands of the Philippine group.

"Although M. Quoy has rightly termed the *Mitra* an 'animale apathique,' I have seen the small longitudinally-ribbed species crawl about pretty briskly over the smooth sand among the low coral islands. The *Mitra episcopalis*, probably on account of the small size of its locomotive disc, and the ponderous nature of its long shell, is a very sluggish Mollusk. I have observed some of the *Auricula*-shaped mitres that live among the Philippines, in the shallow pools left by the receding tide, crawling about the stones out of the water, in company with *Planaxis* and *Quoyia*. The Mitres, like many of the large Volutes, prefer, however, to associate together, and may be seen in dozens crawling over the sandy mud-flats in shallow water, being most active just as the flood-tide makes. When the tide recedes, they bury themselves superficially in the yielding soil, and are with difficulty discovered. Some of the small-ribbed species cover themselves entirely with the sandy mud, and in that disguised condition travel about with comparative security. On one occasion, on the small island of Ambolan, at the south end of Mindoro, I was walking up to my ankles over a firm sandy mud-flat, taking little notice of the *Cones*, *Strombi*, *Meleagrinae*, and *Volutes*, which people the water in great numbers, but looking about anxiously for the rarer mitres, when I first perceived these small species, under their ingenious disguise, marching in towards the shore as the tide flowed rapidly over the level surface. Persons, by the way, should never venture in places of this description barefooted, as there is a species of *Pinna* which buries its sharp end in the mud, but leaves the thin trenchant edges of the gaping

Gastero-
poda.

Gastero-
poda.

extremity exposed, and when trodden on, inflicts very deep and painful incised wounds. Both myself and several of the boat's crew suffered in this way."

"The Philippine Islands would seem to harbour the greatest number of these elegant and beautiful shells, although a great many species were obtained by Mr Cuming in tropical America. They appear to be chiefly confined to the equatorial regions, scarcely any being natives of cold climates. I have met with several among the Meia-co-shima Islands, at Loo-Choo, at Japan, and at the Keeling or Cocos Islands. They are most frequently to be met with in somewhat shallow water among the ledges of rocks, between small islands where the water barely covers the land, and within the shelter of coral reefs; sometimes preferring a clear sandy bottom, and sometimes affecting a hard muddy sandy soil. The transversely ribbed species are frequently found in very deep water, and many were dredged by us in 20 and 30 fathoms at Sooloo and in the China Sea." (Adams.)

FAMILY III.—BUCCINIDÆ.

(Whelks and their allies.)

Branchiæ two. Predatory on other Mollusks.

Genus ANCILLARIA, Lam.—"The animal of *Ancillaria* (fig. 83) is voluminous, covering the entire shell, with the exception of the spire. The head, which is entirely concealed by the reflected portions of the foot, consists of a short, inflated, cylindrical, annulated proboscis, above which is a semilunar veil formed by the dilatation and union of the tentacles; there is no indication of eyes. The mantle lines the shell, and is produced anteriorly into a long siphon. The foot is large and bursiform, the side-edges being greatly extended and reflected over the shell, meeting in the middle on the back. As in *Oliva*, it is deeply fissured anteriorly, forming a semilunar disc before the head, divided by a deep longitudinal groove into two lateral, triangular lobes, acuminate transversely; posteriorly it is bilobed, and is either without an operculum, or is provided with a thin, horny, unguiform one, with apical nucleus, semilunar striæ, and an oval muscular impression.

Fig. 83.
Ancillaria obtusa.

As in *Oliva*, it is deeply fissured anteriorly, forming a semilunar disc before the head, divided by a deep longitudinal groove into two lateral, triangular lobes, acuminate transversely; posteriorly it is bilobed, and is either without an operculum, or is provided with a thin, horny, unguiform one, with apical nucleus, semilunar striæ, and an oval muscular impression.

"Sp. *Ancillaria obtusa* (fig. 83) (Swainson, *Journ. Sci. Lit. and Arts*, vol. xviii., p. 282; Sowerby, species *Conchiliorum, Anc.*, p. 5, fig. 24, 25).—Hab. east coast of Africa, below Port Natal. The specimen taken alive at the above-named locality was of a dirty white colour, marked with dull brown elongated blotches, distributed with scarcely so much regularity as represented in our figure. The operculum is shown above the chief figure.

"The *Ancillariæ* resemble the *Olivæ* in their habits, dwelling among the smooth sands in which they frequently bury themselves. They crawl with a quick sliding motion, and, as they glide briskly along, the tubular cylindrical siphon only is visible, directed backwards and upwards, and even laid flat upon the back; the alar expansions of the foot slightly overlap each other in the middle, and, extending considerably beyond the spire, form posteriorly a loose open sac. It is possible that the dilated lobes of the foot are sometimes extended and serve for swimming, as D'Orbigny has observed in *Oliva Tehuelchana* (*Voy. Amér. Mérid. Moll.*, p. 419, A. A.)." (Adams.)

Genus DOLIUM, Lam. (Tuns).—Head with a long proboscis (fig. 49, a); tentacles *b* subulate, with the eyes at the

outer side of their base; siphon *h* slender, canaliculate; intromittent organ *y* in the male very large, grooved, bent, with a plicate glans; foot *d* produced in front of the head without an operculum; pallial border *i* entire. Shell ventricose, spirally furrowed; spire small; aperture very large; outer lip crenate.

Sp. *Dolium galea* (Helmet-Tun), fig. 49.—Shell and soft parts. About fourteen species have been characterized. The helmet-tun is a native of the Mediterranean; but most of the species are from warmer seas, as those of Ceylon, China, Australia, and Polynesia. They affect reefs and rocky beds, and some of the species acquire a great size.

Genus COLUMBELLA, Lam.—The animal of *Columbella* has a long and somewhat narrow vertically depressed head, with the eyes sometimes placed on the outer side of the base of the tentacles, and sometimes on the outer side of reflected prominences, situated at some little distance from the head. The siphon, long and directed forwards, is considerably dilated at the anterior extremity. The foot is short and pointed posteriorly, and bears a small, semi-transparent, horny operculum, with concentric elements. Anteriorly the foot is often considerably produced beyond the head, where it forms a long, thick, flattened, fleshy, finger-like process. Sometimes it is expanded laterally, when it is truncate anteriorly and furnished with two lateral angular processes.

Sp. *Columbella taniata* (fig. 84).—Hab. Borneo.

Fig. 84.
Columbella taniata.

There are two fillets of square red-brown spots on each whirl, the lower of which is concealed in all but the last whirl. The *Columbellæ* live in shallow water, on sandy flats, or congregating about stones.

Genus HARPA, Lam. (Harp-Shells).—The animal of *Harpa* has a very large foot (fig. 85, d), semicircular ante-

Fig. 85.
Harpa ventricosa.

riorly, divided by lateral fissures from the posterior part *e*, which does not bear an operculum, and is said to be spontaneously detached when the animal is molested; tentacles *b* conical, with the eyes at the outer side of the base; siphon *h* cylindrical, elongate. Shell ventricose, with ribs at regular intervals; spire short; aperture large, notched in front.

Sp. *Harpa ventricosa*, Lam. (*Buccinum Harpa*, Linn.)—Hab. Mauritius. The harp-shells are natives of tropical zones, occurring in the Indian and Pacific Oceans. They are generally brought up from deep water and soft or sandy beds.

Genus BUCCINUM, Lam. (Whelks).—The whelks have a lamellar operculum, with the nucleus external, or sub-central within the outer margin. Shell ovate; spire moderate; mouth oblong; outer lip rather sinuous; pillar

Gastero-
poda.

Gastero-
poda.

rounded; operculum ovate. The silicious teeth of the long tooth-strap are arranged in transverse rows of three, the central or "rachidian" tooth having seven points; the lateral teeth hook-shaped, with the scape tridentate. The animals of *Buccinum undatum* and *Chrysodomus antiquus* are both vended for food in the streets of London under the name of "whelks." They are also dredged for bait. The nidamental capsules of the *Buccinum undatum* are figured in cut 92. (For the anatomy of the whelk see Cuvier, *Ann. du Mus.* xi., pp. 447-457; *Mém. s. l. Mollusq.*, No. 17.)

Genus *EBURNA*, Lam. (*Ivory-Shells*).—An instructive drawing was made of the living *Eburna areolata*, Lamarck, during the voyage of the Samarang. It is described as follows by Mr Adams:—

"Sp. *Eburna areolata*, Lam. (fig. 86) (*Eburna tessellata*, Swainson).—Head flat, extended; tentacles very long and slender; eyes *c* consisting of a yellow iris and black pupil, mounted upon pedunculated swellings on the outer base of the tentacles; siphon *h* large, fleshy, and slightly curved; foot *d* long, fleshy, and robust, acuminate behind and carrying a horny operculum *f*. Colour dull pinkish-white, sprinkled with large, light brown, irregular blotches; siphon and tentacles mottled with spots of the same colour." (Adams.)

The shells of the *Eburnæ* are dense and smooth, having usually lost their periostracum. When recent they bear dark-red spots on a pure white ground. They have been dredged from fourteen fathoms, and are pretty

Fig. 86.
Eburna areolata.

widely distributed; occurring at the Cape of Good Hope, the Red Sea, the Indian Ocean, Japan, China, and Australia.

FAMILY IV.—MURICIDÆ, Woodward.

Animal with a broad foot, much expanded in some; eyes sessile on the tentacles at or near their base; branchiæ two. Shell with a straight anterior canal; aperture entire behind.

Genus *MUREX*, Linn. (*Rock-Shells*).—"Shell ornamented with three or more continuous varices; aperture rounded;

Gastero-
poda.

Fig. 87.
Ficula laevigata.

beak often very long; canal partly closed; operculum concentric; nucleus subspiral. The Murices appear to form only one-third of a whirl annually, ending in a varix; some species have intermediate varices of less extent. The ancients obtained their purple dye from species of *Murex*; the small shells were bruised in mortars, the animals of the larger ones taken out. Heaps of broken shells of the *M. trunculus*, and caldron-shaped holes in the rocks, may still be seen on the Tyrian shore (Wilde). On the coast of the Morea there is similar evidence of the employment of the *M. brandaris* for the same purpose (*M. Boblaye*). (Woodward.)

Genus *PYRULA*, Lam. (*Ficula*, Swainson, Fig-Shells).—Head (fig. 87, *C*) elongated, slender, flattened; tentacles *b* long, subulate, placed at the sides of the front, separated by a wide interval at their base; eyes large, black, and sessile on the outer side of the base of the tentacles; siphon *a* elongated, subcylindrical, and produced; mantle thin and membranous, produced on each side into a rounded lobe *h*, equally reflexed on each side over the shell; foot *d* large, expanded, rounded in front, rather produced on each side of the front edge, expanded, broad and tapering, and not furnished with any operculum.

Sp. *Ficula laevigata* (fig. 87), (Reeve, *Conch. Icon.*, *Ficula*, pl. i., fig. 4; *Bulla ficus*, Linn.; *Pyrula ficus*, Lamarck).—Head and neck pink, varied with scattered yellow spots; mantle bright pink, mottled with white and darker pink; under surface of foot dark purple chocolate, varied with yellow scattered spots. Hab. Sooloo Sea, at the depth of 35 fathoms. The dark chocolate colouring of the under surface of the foot presents a rich contrast with the bright freckled pink of the upper.

Sp. *Ficula reticulata* (Reeve, *Conch. Icon.*, *Ficula*, pl. i., fig. 1; *Pyrula reticulata*, Lamarck).—Head and tentacles white; mantle light pink, marbled and reticulated with darker pink; foot pink, with six large opaque white spots at about equal distances. Hab. west coast of Borneo; from mud at a depth of about 17 fathoms. The head of this species differs from that of the former in being colourless. The mantle is characterized by the same pink reticulated marbling as the foot.

"The *Ficula* is a very lively animal when observed in its

Gastero-
poda.

native element, crawling along with considerable velocity, and, owing probably to the lightness of its shell, able to ascend the sides of a glass vessel, in which I had it captive, with facility. The proboscis is rarely exerted when the animal is in motion, but the long slender tentacles are stretched out to their full extent." (Adams.)

FAMILY V.—STROMBIDÆ, Woodward.

Animal (fig. 88) with pedunculate eyes *c*, and tentacles *b*, from a common elongated base; foot *d* narrow and small, but produced, and subservient to active leaping movements, during which the shell oscillates from side to side; operculum *f* narrow, pointed, and serrated on the outer edge.

Genus STROMBUS, Linn. (*Wing-Shells*).—Shell subventricose; spire short; outer lip dilated into a very ample wing excised towards the canal by a sinus; canal straight, or inflected by the columella obliquely outwards; canal short, emarginate, or truncated; sinus of outer lip distinct from canal; in older shells this lip is expanded into a wing, simple and entire. *Strombus*, Lam.

Sp. *Strombus gigas*, L. (Lister, *Conch.*, tab. 863, fig. 18).—Hab. West Indies. This species forms the largest known univalve shell, weighing sometimes four or five pounds; its apex and spines become solidified by calcareous deposits with age. From its occasional use as a garden ornament it has been called "fountain-shell." Vast numbers are annually imported from the Bahamas for the manufacture of cameos and for porcelain works. Canal elongate; sinus of outer lip not contiguous to canal; the lip produced into digitate laciniae. *Pterocera*, Lam.

Sp. *Strombus Chiragra*, L. (Lister, *Conch.*, pl. 870, fig. 24); *Strombus scorpius*, L. (D'Argen., *Conch.*, pl. 14, fig. B.)

Genus ROSTELLARIA, Lam. (fig. 88).—Shell with a long spire; whorls numerous; canal subulate, extending behind up the spire; sinus of outer lip contiguous to the canal. The Eocene fossil species have the outer lip enormously expanded.

Sp. *Rostellaria rectirostris*.—The subcylindrical annular proboscis (fig. 88, *a*) has a broad central dark-

Fig. 88.
Rostellaria rectirostris.

bronze line, the edges of which are yellow, bordered with vermilion; eyes *c* deep blue, with black pupils, surmounted on long cylindrical peduncles; tentacles *b* white, with a narrow vermilion streak along their anterior surface; body cylindrical and much elongated, marked with red-brown on the outer surface, white beneath; foot *d* narrow, rather dilated and rounded in front, with a thickened anterior margin, small and subquadrate behind, separated by a deep notch from the lid-bearing part *e*; operculum *f* ovate-triangular, annular, horny, semitransparent.

The *R. rectirostris*, like the rest of the *Strombidae*, progresses by bending the foot under the shell and sud-

denly straightening, which enables it to roll and leap over and over. (Adams, *loc. cit.*)

Genus TEREHELLUM, Klein., Lam.—The discovery of the living *Terebellum* has occasioned the removal of that genus to this family, on account of its affinity with *Strombus*. The eyes are pedunculated, and the mantle is characterized by the same peculiar divided edge. In the narrow form of the foot and proboscis-like head it is allied to *Struthiolaria* and *Aporrhais*, and, like *Oliva*, the mantle has a long filamentary cord winding into the sutures of the shell.

Sp. *Terebellum subulatum* (fig. 89), Lamarck (*Anim.*

Fig. 89.
Terebellum subulatum.

sans vert., Deshayes' edit., vol. x., p. 584).—Hab. China and Sooloo Archipelago.

"The animal of *Terebellum* may be thus described: Head probosciform *C*; tentacles connate with the long cylindrical eye-peduncles, at the ends of which are placed the eyes *b*, *b*; mantle with the right edge reflexed over the outer lip, produced in front into a short siphon *a*, and furnished behind with three or four filaments, the inner edge spread over the columella, and ending behind in a long slender filament, which occupies, as in *Oliva*, the channelled suture of the spire; foot large, ovate, fleshy, laterally compressed, with a lobe at the fore part, rounded behind, and bearing a minute, horny, triangular operculum *f*.

"The eye-peduncles of this species are finely dotted with brown, the proboscis and the fore part of the body is punctulated with the same; the rest of the body is opake white, with three large irregularly-shaped red-brown blotches on the fore part; the under surface of the foot is light brown, with a white subcruciate marking.

"The *Terebellum* is extremely shy in its movements. Poising its shell in a vertical position, and cautiously protruding its longest telescope-eye from the truncature in the front of the shell, it will remain stationary until assured of security. It will then use its pointed foot as a lever and roll its shell over and over, progressing by a series of irregular leaps. When removed from the water, before dying, it will jump several inches from the ground. Mr Cuming assures me his knowledge of the animal coincides with my own experience, and that on one occasion he lost a fine specimen owing to its suddenly leaping from his hand into the water. I have observed both the varieties of this species alive. In the spotted variety, the muzzle is reddish towards the tip, the body is opake pearly white, the eye-peduncles mottled with dark red; in the common variety there are three large red-brown blotches on the fore part of the body." (Adams.)

With these active forms of carnivorous Gastropods, we seem to reach the summit of this branch of the great Molluscan tree.

The ova of the marine Gastropods are enveloped, before exclusion, in mucous capsules; prepared by a special gland situated near the termination of the oviduct. The secretion in some species is soft, flexible, and transparent; in most it hardens by contact with the sea-water, and assumes various definite and characteristic forms; the nidus is sometimes simple, sometimes compound, but each compartment contains

Gastero-
poda.

Gastropoda.

many ova; and the development of the embryo proceeds in the nidamental chamber until its own little defensive shell is acquired.

In the terrestrial Gastropods the ova are usually spherical and opaque, and separately extruded: snails and slugs oviposit in the earth. The tropical *Bulinus*¹ cement leaves together to form an artificial nest for their large eggs.

Fig. 90 is an outline of the egg of the *Bulinus ovatus* of the natural size. The shell of the embryo is an inch in length when it is excluded. Specimens of both egg and young of the species are preserved in the Cumingian collection.

The ova of the sea-slug (*Tritonia*) are expelled together in the form of a long thread, and are arranged in a spiral manner in the tenacious transparent covering of the thread. In the *Doris muricata* the ova are aggregated in a flattened spirally disposed albuminous band when excluded from the oviduct.

The harder albuminous capsules which defend the ova of other marine Gastropods offer a great variety of forms, some of which are remarkable for their complexity, others for their symmetry and beauty. The nidamental sacs of the frail *Ianthina* (fig. 91, *b*)

Fig. 90.
Bulinus ovatus.

Fig. 91.
Ianthina.

are of a flattened pyriform shape, composed of a delicate reticulate film of albumen, and are attached by one extremity to a float *a*, formed likewise by a secretion of albuminous matter, dilated into a discoid group of cells filled with air. To this float the parent *Ianthina* commits her little progeny, and having securely fastened their several cradles or nursery cells she detaches the float, which bears the ova to the surface, and sustains them where they may best receive the full influence of solar light and heat. The nidamental capsules of the *Pyrula rapa*² are attached in regular linear series to portions of decayed wood; they are of a flattened sub-conical figure, adhere by their apex, and have their base emarginate. The nidamental capsules of the whelk (fig. 92), are common objects on our sea-shore; they are aggregated in large irregular masses, often attached to portions of oyster-shell; each capsule presents a depressed ovoid figure, with one side convex, the other

Fig. 92.
Egg-capsules of the Whelk (*Buccinum*).

flat or concave. The upper figure opposite the left hand shows the round hole in the inner side of the capsule, whence the young has escaped; the figure to the right is the shell of the embryo magnified four diameters. (Woodward).³ The small nidamental cells of the cowry (*Cyprea*) are aggregated in a flattened group. In the *Turbinella* the cells are of a flattened subpentagonal form, and adhere

together, superimposed one upon the other, forming what is termed a camerated nidus. Each chamber contains between twenty and thirty embryos. The rudimental shell is completely calcified and fitted to defend the little Gastropod before it emerges from the temporary shelter provided for it by the parent. Numerous other modifications of these secreted nests of the Gastropodous Mollusca might be enumerated.

The development of the Gastropods has hitherto been traced in a few apneustal, nudibranchiate, tectibranchiate, pulmonate, and pectinibranchiate species; and the results show considerable modifications in its course and phenomena. Most Gastropods are oviparous; some species of *Litorina* are ovo-viviparous; *Paludina* and *Clausilia ventricosa* are viviparous.

With the singular exception observed in *Buccinum*, in which the segmental or granular germ-mass from which the embryo is developed results from a confluence of numerous, perhaps fifty, previously distinct germ-masses in the nidamental capsule, that germ-mass is due to progressive segmentation of the yolk, the result of the usual multiplication of germ-cells, which clothe themselves with the so subdivided but coherent yolk-substance. One cell in *Pulmonata* and *Aplysia*, indeed, is from the beginning conspicuously larger than the rest, and has been called the directive cell (*richtungs-blaschen*).

In all Gastropods the germ-mass takes the form of a large round embryo, one end of which becomes indented and clothed by ciliated epithelium, by which it rotates on its axis in the albumen of the egg. Sars, who noted the oviposition of the *Tritonia Ascanii* on the 1st of February 1840, traced the segmentation of the yolk to the 8-fold division on the 4th day, and the completion of the germ-mass on the 8th day. The indentation producing the bilobed end of the embryo took place on the 15th day; after which the ciliated lobes extended outwards, and assumed the form of wings or vela (fig. 93, *c, c*). Dr Grant had long before discovered the corresponding ciliated vela in the embryos of *Purpura*, *Trochus*, *Nerita*, *Doris*, and *Æolis*. On the 20th day the rudiment of the foot appeared beneath the bases of the vela, and on the 22d a transparent shell *s* was developed, which covered all the body save the ciliated vela and foot. "I could scarce believe my eyes," writes Sars, "when I made this discovery." As the body and shell enlarge and elongate, the cilia become stronger on the lobes, and the active movements of the embryos, crossing each other like midges in the clear albumen of the nidamental band, offer a most singular spectacle; the vela now move by muscular contraction, alternately approximating and stretching outwards. On the hinder part of the foot is an operculum (fig. 93, *f*), which closes the mouth of the shell when the embryo retracts itself. Among the internal organs the acoustic capsules appear first, then the eyes. The tentacles next protrude, and the border of the mantle appears. The mouth is established between the vela. On the 36th day the stomach and a looped portion of intestine come into view out of the germ-mass, the remnant of which is chiefly changed in the hepatic and genital glands. A longitudinal muscle for retracting the body into the shell also now appears. During this course of development the nidamental band has become, by endosmose of sea-water, three times as thick as before. The albuminous substance is absorbed by the embryos; they respire by the reaction of their ciliated surface on the imbibed water. As they

Fig. 93.
Embryo *Æolis*.

Gastropoda.

Gastero-
poda.

grow they with difficulty find room for their revolutions, and between the 32d and 38th days rupture the delicate membrane of their nest, and struggle out. They are now about one-eighth of a line in length, and swim by ciliary action, the vela being kept stiffly outstretched. They survived in the vessels of daily renewed sea-water two weeks, then died, their embryo shells floating on the surface.

The ova of the *Aplysia* are excluded in a long string, enveloped by a transparent flexible mucus, in the centre of which they are aggregated in several irregular series. When examined at this period, the yolk has apparently divided itself into six, seven, or more numerous globules, or, in other words, as many germinal vesicles, included in the same mass of albumen and in a common chorionic coat have given origin to as many aggregations of vitelline cells. These, therefore, may be regarded as so many independent yolks, in each of which the same progressive fissiparous multiplications have been observed as in the single vitellus of the ovum of the *Planorbis* and of animals in general.

After the multiplication of the globules has gone on to a certain point, two of them, of larger size than the rest, indicate, one the seat of the future branchial organs, the other that of the muscular mass.

The ciliated epithelium, with which the vitellus is now almost entirely covered, occasions the usual rotations of that body. The process of transformation of this monad-like embryo to the gastropodous form resembles closely that which has been described in *Tritonia*. The remains of the vitelline mass not yet metamorphosed into special organs indicate the expanded alimentary sac. The rudimental foot, and the velum with its strongly ciliated border, protrude from a rudimental, thin, pellucid, and flexible shell, which covers all the rest of the surface of the body. The embryo describes elliptical revolutions in the chorionic cavity. As development proceeds and the embryo increases in size, the shell acquires a more distinctly turbinated form, and is slightly bent out of its vertical plane. An operculum is formed upon the protruded surface of the foot. The course of internal development accords with that in *Tritonia*. The ciliated branchial surface begins to be withdrawn more into the interior; and in this state, protected completely by an external shell, the young *Aplysia* is launched into the ocean.

Truly may the subsequent growth, which effects an entirely internal position of the shell, with such a mutation of its form that the primitive nucleus can scarcely be detected upon the almost flattened plate, now destined to protect the equally internal respiratory organs of the mature animal,—justify us in applying to it the term “metamorphosis.” This term is still more applicable to the developmental phenomena in the *Tritonia* and *Doris*, since these Gastropods, which are not only naked like the *Aplysia*, but are devoid of any internal rudiment of a shell, are yet provided with a delicate, little, operculated, nautiloid, horny, external shell, in their young state. The same general course of development in which the embryo or larval Mollusk is provided with the ciliated lobes and operculated shell, has been traced by Lovén in *Æolis*, *Bulla*, *Cerithium*; by Lund in *Murex* and *Natica*; by Nordmann in *Tergipes*; by Allman and Vogt in *Actæon*; by Carus in Pteropods; and by Siebold in *Vermetus*. Rudiments of the vela are retained in *Tergipes*, *Æolis*, *Doris*, *Tritonia*, and *Aplysia*; and in *Thetys* they continue in almost their primitive form and proportions, unless the broad head-lobes of the adult be substituted for the embryonal vela, as is the case with the fins of the Pteropods; otherwise the little *Cymbulia*, with its delicate, symmetrical shell (fig. 39), would represent a persistent embryo form of the higher Gastropodous *Encephala*.

Cephalo-
poda.

Professor Müller has detected ova and embryos of a Gastropod, which he believes to belong to a species of *Natica*, within the body of the *Synapta digitata*. They were contained in elongated sacs, firmly attached or fused at one end to the head, at the other end to the gut, of the *Synapta*. The upper portion of the sac contains both spermatozoa (like those of *Natica*) and ova; the lower portion of the sac was intus-suscepted with a blind end, and this contained the ova, with developed embryos, according to the velated type. This remarkable discovery indicates some singular parasitic habit in the generative economy of the Mollusk.

The development of the pulmonated Gastropods proceeds without any such metamorphosis as that above described. In the testaceous species its course has been ably traced by Prevost and Dumortier in *Limnea*, by Pfeiffer in *Helix*, by Jacquemin and Quatrefages in *Planorbis*, and by Oscar Schmidt and Gegenbauer in *Helix*, *Clausilia*, and *Limax*.

The whole yolk is transmuted into a germ-mass. This becomes partially divided into a pallial or visceral and a pedial or somatal lobe. The fore part of the pallial portion dilates into a contractile sac, by Gegenbauer deemed the homologue of the “velum” of pectinibranchiate embryos. A similar contractile sac is formed at the end of the pedial lobe; and the contractions of the two sacs alternate, producing a flux and reflux of fluid pabulum before the heart is developed. A peculiar gland is attached to the pallial sac. The first granular rudiments of the shell are deposited in the substance of the mantle. The anterior tentacles and the parts about the mouth are the last to be completed.

CLASS VI.—CEPHALOPODA, Cuvier.

Encephalous Mollusks, with locomotive and prehensile organs radiating from the head; diœcious and ametabolan. Animal divided into a somatal and pallial (fig. 94, *m*, *o*) portion. The former is chiefly muscular (fig. 94, *f*, *h*). It contains the organs of sense, mastication, and deglutition, and supports the organs of prehension and the chief powers of locomotion. It is called the “head” (fig. 97, *a*, *c*). The pallial division (fig. 97, *a*, *bb*), termed “trunk,” or abdomen, consists of a more or less muscular sac or mantle, with a transverse anterior aperture, from which an expiratory siphon or “funnel” projects; and it contains the respiratory, generative, and digestive organs. The branchiæ are pinnatifid and concealed. The sexes are distinct. All Cephalopods are oviparous. As far as observation has extended, a part only of the yolk is assimilated into a germ-mass; and development is progressive, without metamorphosis, to the completion of the miniature Cephalopod *in ovo*.¹

ORDER I.—TETRABRANCHIATA, Owen.

Branchiæ in two pairs, without branchial hearts; funnel formed by a convolute muscular plate; mantle thin, and feebly muscular; no ink-bag; arms very numerous, hollow, and with retractile tentacula; mandibles with calcareous tips; eyes pedunculate; head retractile, within a shell, which is external, many-chambered, siphunculate, the outer layers porcellaneous, the inner layers and partitions nacreous.

Genus NAUTILUS, Linn.—Shell discoid, symmetrical, with the apertures, sutures, and siphuncle, simple. The anatomical characters of the order are also those of the sole existing genus. It is the representative of numerous genera and species of chambered Cephalopods that abounded in the Palæozoic and Secondary periods, but which seem to

¹ See Köl liker's masterly *Entwicklungsgeschichte der Cephalopoden*, 4to, 1844.

Cephalopoda.

have been superseded, as carnivorous Mollusks, in the Tertiary and recent periods, by the Pectinibranchiate Gastropods.

The organization of the Pearly Nautilus (*Nautilus Pompilius*), first made known in 1832,¹ throws light upon that of the extinct *Ammonites*, *Orthoceratites*, *Lituites*, *Turritulites*, &c., and possesses, therefore, an extrinsic interest, besides that which arises from the peculiar modifications of Molluscan structure which it presents. The soft parts (fig. 94, *t, o*) form an oblong mass, divided by a constriction into two slightly unequal segments; the posterior (*m* to *o*) is smoothly rounded, soft, and membranous, containing the viscera, and adapted to the last chamber of the shell; the anterior (*m* to *t*) is densely muscular, and includes the organs of sense and locomotion. It can be retracted within that chamber, as is shown in fig. 94, which is here selected as

Fig. 94.
Nautilus Pompilius.

showing the relations of the soft parts of the Pearly Nautilus to the shell in a specimen in which those relations had never been disturbed. The subject dissected and described by Professor Owen in 1832 consisted of the soft parts only, and their relations to the shell were determined on anatomical grounds, as they are illustrated in plate 1 of the *Memoir* above cited. The author's deductions were contested by Dr Gray, in the *Philosophical Transactions* for 1833, p. 774; by Professor R. Grant, in the *Lancet*, 1833, pp. 506 and 509; and by M. de Blainville, in the *Nouvelles Annales du Muséum*, tom. iii., p. 7. The second specimen of the Pearly Nautilus, which was brought to Europe in 1838, consisted also of the soft parts only. It was described by Professor Valenciennes,² who adopted Professor Owen's conclusions as to their relative position to the shell. The third specimen, brought to England by Captain Sir Edward Belcher, R.N., in 1842, was contained in the shell, but not attached. It had been taken out, and been replaced in the position it originally occupied, according to Sir E. Belcher's convictions. That position agreed with the figure in plate 1 of Professor Owen's *Memoir*. The present figure, from a drawing in the possession of Dr Gray, F.R.S., is from a specimen in the British Museum, naturally attached to and retracted within the shell, a portion of which has been removed to show the soft parts; and the principal viscera are indicated in outline.

The mantle is very thin upon the posterior part of the

body. It is continued backwards in the form of a slender tube, which penetrates the calcareous siphon in the septum closing the occupied chamber behind, and is thence continued, as the membranous siphon, through all the other divisions of the shell to the central nucleus. As the mantle advances towards the anterior part of the abdomen it increases in thickness, becomes more muscular, extends freely outwards (*m*), and forms a wide concave fold in the dorsal aspect, which is reflected over the black-stained involuted convexity of the shell *s*. The margin or collar of the mantle is continued downwards and forwards on each side with a sinuous outline, and is perforated below for the passage of the muscular expiratory and excretory tube called the "funnel" *f*. In the female *Nautilus* the nidamental glands form two circular convexities on the ventral surface of the abdomen, behind which the mantle is encircled by a thin layer of brown matter, like the periostracum, which is very narrow above and below, but expands on each side into a broad plate *a*, corresponding in size and form with the surfaces of attachment of the two great muscles for adhesion to the shell.

The somatal division forms a strong and wide sheath, containing the mouth and its more immediate appendages; its inner surface is for the most part smooth, the outer one divided and extended into many parts or processes. The chief of these forms a broad triangular muscular plate or hood *h*, covering the upper part of the head, and presenting a middle and two lateral superficies; the former being traversed by a median longitudinal furrow, indicating the place of confluence of the two large hollow tentaculiferous processes of which it is composed. The back part of the hood is excavated for the lodgment of the involuted convexity of the shell, and the above-described fold of the mantle *s* covering it. Each side of the head supports a group of perforated processes or digitations *t*, the largest of which is next the hood, and the rest decrease in size as they descend in position. Exclusive of the short subocular perforated process, and of the confluent pair forming the hood, the digitations are eighteen in number on each side, and are of a conical form; each contains a long and finely annulated tentacle, with the inner surface supporting narrow, close-set transverse plates.

To the nineteen tentacula which are supported by the confluent and free digitations on each side of the head, two others must be added, which project from very short sheaths, one before, the other behind, the eye; the lateral transverse incisions are deeper in these than in the digital tentacles. The eyes are about the size of hazel-nuts, and are attached each by a short peduncle to the side of the head, behind the digitations, and a little below the margin of the hood. The inferior surface of the oral sheath is excavated for the lodgment of the infundibulum *f*. It appears that, amongst other remarkable peculiarities of the *Nautilus*, is its possession of external ears. Mr Macdonald writes:—"Both Professors Owen and Valenciennes noticed that the hollow subocular process of their specimens of *Nautilus Pompilius* was not tentaculiferous, and I may be permitted to say that this was also true of several specimens of *Nautilus Pompilius*, and one of *N. macromphalus* examined by me. But there is still another matter worthy of remark with reference to this process, namely, that its cavity may be traced downwards, inwards, and a little forwards, to within about the

Cephalopoda.

Cephalopoda.

twentieth of an inch of the auditory capsule; indeed it would appear as though provision had been made for the entrance of sonorous waves through a rudimentary external ear." "The interior of the tube is lined with a glandular membrane, thrown into small folds disposed longitudinally."¹

The mouth is armed with two mandibles, shaped, as in other Cephalopods, like the beak of a parrot reversed, the lower mandible overlapping and curving upwards beyond the upper one. Both mandibles are horny, with their tips encased by dense calcareous matter, and their base implanted in the thick muscular parietes of the mouth.

They are immediately surrounded by a circular fleshy lip with a plicated anterior border, external to which there are four broad flattened processes continued forwards from the inner surface of the oral sheath, two of which are superior, posterior, and external, the other two are inferior, anterior, and more immediately embracing the mouth; the latter are connected together along their inferior margins by a middle lobe, the inner surface of which supports a series of longitudinal lamellæ. On the inner surface of the oral sheath beneath these processes there are two clusters of soft conical papillæ, and on each side of these a group of lamellæ. Each of the four processes, which are called "labial," is pierced by twelve canals, the orifices of which project in the form of short tubular processes from the anterior margin, and each canal contains a tentacle similar to, but somewhat smaller than those of, the digitations. Thus the number of tentacula with which the Pearly Nautilus is provided, amounts to not less than ninety, of which thirty-eight may be termed digital, four ophthalmic, and forty-eight labial.

All Cephalopods have an internal cartilaginous skeleton: that of the *Nautilus* is confined to the inferior surface of the head; no part of it extends above the œsophagus. Viewed sideways, it presents a triangular form; a portion of the annular brain is protected by a groove on the upper surface of the cartilage; two strong processes are continued from its anterior and superior angles into the crura of the infundibulum, giving origin to the chief muscles of that part. Two other thinner processes are continued backwards, and curve inwards and downwards: they give origin to the two great muscles which pass from the internal to the external skeleton, or, in other words, attach the animal to the shell.

The muscular fibres of the "soma" or oral sheath arise from the whole of the anterior or outer part of the internal skeleton. The muscular structure of the funnel presents a much greater development than in the naked Cephalopods; and, from its relation to those masses which, on the one hand, attach the soft parts to the shell at *a*, and, on the other, connect the head to the trunk, we may conclude that the funnel is the principal organ of natation, and that the *Nautilus* is propelled, like the *Octopus*, by a succession of jerks occasioned by the re-action of the respiratory currents upon the surrounding water. The orifice of the funnel is guarded by a valve.

The principal masses of the nervous system are concentrated in the head, and are more or less inclosed by the cephalic cartilage. The superœsophageal portion is a thick transverse rounded chord, connected at each extremity with three ganglionic masses; the middle and superior of these (ophthalmic ganglions) supply the eyes; the anterior and inferior pair are united below the œsophagus; the posterior and inferior pair form a second œsophageal nervous centre. The nerves given off immediately from the superœsophageal mass supply the muscular and other parts of the mouth, and have small buccal ganglions developed upon them. The anterior œsophageal ring gives off principally the nerves to the tentacula, and the two median ones are connected with a ganglion, which supplies the tentacula of

Cephalopoda.

the inferior labial processes and the lamellated organs on that part of the oral sheath. The tentacular nerves are continued, like those of the arms in the higher Cephalopods, along the middle of the tentacle, attached by loose cellular tissue to the vessels of the part. The posterior collar gives off numerous nerves of a flattened form, which supply the muscles of the shell. The respiratory nerves form a small ganglion at the base of each pair of gills, from which branches are sent to those organs, to the heart, and to the appendages of the veins. A plexus of more delicate visceral nerves is continued backward along the interspace of the branchial nerves, and the chief branches are connected with a small ganglion situated between the cardiac and pyloric orifices of the stomach.

The calcareous extremity of the upper mandible is sharp-pointed and solid to the extent of five lines. The lower mandible is sheathed with a thinner layer of the hard white substance, which forms a dentated margin. The fossils termed "rhyncholites" are the homologues of these calcareous extremities of the beak in cognate extinct Cephalopods. The muscular subspherical mass, which supports and moves the mandibles, is provided with four retractors, and can be protruded by a strong semi-circular muscle, which is continued from the margin of one of the inferior labial processes over the mandibles and their retractor muscles to the labial process of the opposite side.

The glottidium is supported by a horny, slightly curved, and transversely striated plate. The fleshy substance forms three distinct papillose caruncles anteriorly, or "tongue" proper, into which the retractor muscles are inserted. The tooth-strap supports four longitudinal rows of recurved spines, behind which the surface of the glottidium is again soft and papillose. Two broad duplicatures of mucous membrane project forwards from the sides of the pharynx; they each include a simple layer of salivary follicles, the secretion of which escapes by a single perforation in the middle of the process.

The lining membrane of the pharynx is disposed in numerous longitudinal folds, where it begins to contract into the œsophagus. This tube, having passed through the nervous collar, dilates into a capacious crop (fig. 94, *c*), from the bottom of which a contracted canal, half an inch in length, is continued to an oval gizzard *g*. The intestine commences near the cardiac orifice, and soon communicates with a small, round, laminated pouch, through which the biliary secretion passes to the intestine. This tube forms two abrupt inflections, and terminates in the branchial cavity near the base of the funnel close to the proboscidian end of the oviduct.

The epithelium of the œsophagus and ingluvies is developed into a thick cuticular membrane, with minute ridges in the gizzard. In the specimen dissected by the writer, the crop and gizzard were laden with the fragments of a small crab, the pieces being more comminuted in the gizzard.

The liver *l* is a bulky gland, extending on each side of the crop as low down as the gizzard; it is divided into four lobes, connected posteriorly by a fifth transverse portion: the lobes are subdivided into numerous lobules of an angular form. The secretion of the bile is derived, as in other Mollusks, from arterial blood; it is conveyed from the liver by two main trunks, which unite into one duct, about two lines from the laminated sac. The bile, having entered the sac, is diverted by a peculiar development and disposition of one of the laminæ from flowing towards the gizzard. The follicular structure of this and the other folds of membrane indicate their glandular character; and the entire laminated pouch may be considered as a more developed form of pancreas than the simple cæcum which represents that gland in some of the Gastropods. No other foreign

¹ *Proceedings of the Royal Society*, 1856, p. 381.

Cephalopoda. secretion enters the alimentary canal, as there is not any ink-gland in the Pearly Nautilus.

The heart and large vessels, with their follicular appendages, are contained in a large cavity opposite the letter *h*, subdivided into several compartments. Some of these contain groups of follicles developed from the veins proceeding to the branchiæ, and they communicate by small apertures with the pallial cavity. Sea-water is thus admissible into the pericardium, and thence into the siphuncle. Any matter excreted from the venous follicles, which seem homologous with the so-called "renal gland" of lower Mollusks, may escape by the above apertures into the pallial cavity. The principal venous trunk, returning the blood from the soma, is separated from the abdominal cavity by a layer of decussating, chiefly transversely disposed, muscular fibres. There are several small intervals left between the muscular fibres and corresponding round apertures in the venous tunics. These communications with the general abdominal cavity are similar to that discovered by Cuvier in the *Aplysia*. M. Valenciennes detected the same structure in the specimen of the *Nautilus* dissected by him. The blood from the diffused abdominal venous sinus is thus received into the chief vein proceeding to the gills.

The branchial circulation may be considered to commence when the blood again begins to move from trunk to branches, four of which trunks are continued from the terminal venous sinus to convey the carbonized blood to the four gills, of which there is a larger and a smaller one on each side. Each pair of gills, situated opposite the letter *b* in fig. 94, is connected by a common peduncle to the inner surface of the mantle; the larger branchia consists of a central stem supporting forty-eight vascular plicated lamellæ on each side; the smaller branchia has thirty-six similar lamellæ on each side.

The four vessels continued from the venous sinus have attached to them, in their course to the gills, the clusters of glandular follicles above mentioned. The veins extend beyond the follicles each to the root of its respective gill, where it receives a small vein. At this part there is a valve which opposes the retrogression of the blood; the vessel, which may now be termed branchial artery, penetrates the root of the gill, and dilates into a wider canal, which is continued through the soft white substance forming the branchial stem. A double series of branches are sent off from the lateral lamellæ, which ramify and subdivide to form the capillary plexus, from which the returning vessels terminate in the branchial vein. These veins quit the roots of the gills, and return to terminate at the four corners of a subquadrate transversely elongated ventricle. From this ventricle two arteries arise, one anterior, the other posterior, of large size, and with a muscular bulb at its commencement, with which is connected an elongated, pyriform, apparently closed sac.

The female organs of the *Nautilus* consist of an ovary, an oviduct, and, as in the Pectinibranchiate Gastropods, of an accessory glandular nidamental apparatus. The ovary is situated on the right side of the gizzard in a peritoneal cavity peculiar to itself. It is an oblong compressed body, one inch and a half in length, and an inch in breadth; convex towards the lateral aspect, and on the opposite side having two surfaces sloping away from a middle longitudinal elevation. At the anterior and dorsal angle there is an orifice about three lines in diameter, with a puckered margin, which conducts into the interior of the ovary. It is filled with numerous oval ovisacs of different sizes, which are attached by one extremity to the ovarian capsule, but are free and perforated at the opposite end. The oviduct terminates at the base of the funnel near the anus. The nidamental gland consists of numerous close-set pectinated

laminae. An interesting account of the dissection of a male *Nautilus Pompilius* has been contributed by Professor Van der Hoeven to the fourth volume of the *London Zoological Transactions*, p. 21. Professor Vrolik has published a good description and figures of a specimen in his collection, from Amboyna, in the tenth volume of the *Mémoires de la Société Linnéenne de Normandie*, 1855.

In contrasting the organization of the *Nautilus* with that of the inferior Mollusca, already treated of, we find the main advance to have been made in the organs of animal life.

A true internal skeleton is established in the *Nautilus*, and thus the lowest Cephalopod offers an approximation to the vertebrate type, which not even the highest of the articulate series had attained. Perfect symmetry now reigns throughout the animal and vital organs. The muscular system forms a larger proportion of the body, with various arrangements and complications unknown in the lower Encephalous Mollusks. The respiratory tube, though still completed by the overlapping, not by the coalescence, of its side-walls, has received an enormous development as contrasted with the siphonated Trachelipods; and, by its powerful muscles, and their firm cartilaginous basis of attachment, would seem to be endowed with a new function, in relation to propelling the Cephalopod with its testaceous dwelling through the sea.

The nervous centres concentrated in the head have received a marked increase of bulk, which, nevertheless, is still manifested more strongly in the inferior masses, and especially in the anterior suboesophageal ring than in the superior or cerebral part. Here, however, we find for the first time in the Molluscan series, especial ganglions subordinated to the greatly enlarged organs of vision.

The organs of reptation, which had progressively advanced (as Lamarck's denomination of the higher Gastropods indicates) towards the head, are exclusively attached to that part in the *Nautilus*, and project from before the eyes and mouth. The mouth, besides its jaws and spiny tongue, is now served by organs of prehension; and it is most interesting to observe that these cephalic, prehensile, as well as exploratory, tentacula, at their first appearance manifest the vegetative character in their multiplied repetition and comparative simplicity, compared with their homologues in the Dibranchiate Cephalopods.

Some of the Gastropods have a pair of jaws working upon each other, but in the horizontal plane, as in insects. In the *Nautilus* they are opposed to each other vertically, as in the vertebrate series, and they present a form which is repeated amongst fishes by the *Scari*, amongst reptiles in the *Chelonia*, and almost universally in the class of Birds. The close resemblance to the latter class which the *Nautilus* offers in the modifications of the alimentary canal is sufficiently striking, but hardly more so than some of the *Bryozoa* present, in which radiated animalcules may be discerned one of the roots of the great Molluscan branch of the Animal Kingdom.

In the very few Conchiferous Gastropods that are able to swim the shell is of diminutive size, of a simple form and structure, and of an extremely light and delicate texture. The strong and muscular occupant of the Pearly Nautilus shell would seem to have that abode adapted for occasional natation by the air-chambers and siphuncle. The first living specimen which was captured and brought to Europe in a state fit for dissection was observed floating on the sea with the shell upwards,¹ and was obtained by the boat-hook. The parts of the shell, progressively vacated during the growth of the animal, are successively partitioned off by smooth plates concave towards the outlet. The formation of these proceeds from the circumference to the centre, and there meeting with the siphuncular

Cephalopoda.

¹ Owen, *Memoir*, ut supra, 4to, p. 7.

Cephalopoda.

prolongation of the mantle, which retains its primitive connection with the shell-nucleus, calcification is continued backwards for a short distance around that process, which now forms the membranous siphon, and acquires the partial protection of the calcareous tube. An air-tight chamber is thus formed, traversed by the siphon; by a repetition of the same processes a second chamber is formed, included within two perforated septa; and similar, but wider partitions continue to be added, concurrently with the formation of the new layers which extend and expand the mouth of the shell, until the animal acquires its full growth, which is indicated by the body having receded for a less distance from the penultimate septum before the formation of the last septum is begun.

The periodical formation of these septa in the progress of growth is analogous to that of the projecting external plates in the Wendletrap, and of the rows of spines in the *Murex*; but these external processes consist of the opaque calcareous layer of the shell, whilst the internal processes in the *Nautilus* consist of the nacreous layer like the septa in the *Turritella*. Thus the embryo *Nautilus* at first inhabits a simple shell like that of most univalve Mollusca, and manifests, according to the usual law, the most general type at the early stage of its existence; although it soon begins, and apparently before having quitted the ovum, to take on the special form.

In acquiring the cambered structure of the shell, the *Nautilus* gains the power of rising from the bottom, and the requisite condition for swimming; by the exhalation of some light gas into the deserted chambers, it attaches to its otherwise too heavy body a contrivance for ascending in its atmosphere, as we ascend in ours, by the aid of a balloon. But the *Nautilus*, superior to the human aeronaut, combines with the power of elevating and suspending itself in the aqueous medium, that of opposing its currents and propelling itself at will in any direction. It possesses the latter essential adjunct to the utility of the balloon as a locomotive organ, by virtue of the muscular funnel; through which it ejects into the surrounding water, doubtless with considerable force, the respiratory currents.

It appears that the proportion of the air-chambers to the dwelling-chamber of the *Nautilus* and its contents is such as to render it of nearly the same specific gravity as the surrounding water. The siphon, which traverses the air-chambers, communicates with the pericardium, and is most probably filled with fluid from that cavity. It certainly conducts small blood-vessels, which are essential to the maintenance of the vitality of the chambered part of the shell.¹

In air a large and perfect shell of the *Nautilus Pompilius* weighed six ounces and a-half avoirdupois; it required an additional weight of one ounce seven drams to sink it in water. The soft parts of a female Pearly Nautilus weighed, in air, five ounces; but the specific gravity, including the contents of the crop, was nearly that of sea-water.

The power by which the *Nautilus* alters its specific gravity is probably like that possessed by the fresh-water testaceous Gastropods, depending chiefly upon changes in the extent of the surface which the soft parts expose to the water, according as they may be expanded to the utmost, and spread abroad beyond the aperture of the shell, or be contracted into a dense mass within its cavity. The *Nautilus* would likewise possess the additional advantage of producing a slight vacuum in the posterior parts of the chamber of occupation which is shut out by the horny cincture and muscles of adhesion from the rest of that cavity; and it is possible that the gas in the last air-chamber might expand as the *Nautilus* protrudes from the shell, and be in the same degree condensed as it forcibly drew itself back.

Whatever additional advantage the existing *Nautilus*

might derive, by the continuation of a vascular organized membranous siphon through the air-chambers, in relation to the maintenance of vital harmony between the soft and testaceous parts, such likewise must have been enjoyed by the numerous extinct species of the Tetrabranchiate Cephalopods, which, like the *Nautilus*, were lodged in chambered and siphoniferous shells.

Sp. *Nautilus Pompilius* (Pearly Nautilus).—This species ranges from the Persian Gulf and Indian Ocean, to the Chinese Seas and Pacific.

Sp. *Nautilus scrobiculatus* (Umbilicate Nautilus).—Hab. the warmer latitudes of the South Pacific.

Sp. *Nautilus macromphalus* (Widely Umbilicate Nautilus).—Hab. New Caledonia, and neighbouring isles of the South Pacific.

It is not certain to which of the above species the following remark, on their abundance, applies:—"The Pearly Nautilus is so abundant, that its shell serves the Papouans of Port Praslin in 'Nouvelle Bretagne,' and throughout the Papouan Archipelago, as a scoop to bale out the water from their canoes; the debris of the shell cover the shores of those islands."²

If the *Nautilus* extended itself in a straight line during its growth, instead of revolving round an imaginary axis, a straight conical shell would be produced, with the chambered part divided by simple septa concave next the outlet. Such are, in fact, the characters of the fossil shells called *Orthoceras*.

The margins of the septa of the shell in all the existing species of *Nautilus* are slightly sinuous, which makes the surface next the aperture of the shell convex at one part and concave at another. In an extensive genus of extinct chambered shells called *Ammonites*, the sinuosity of the margins of the septa is much greater, and most of the surface next the outlet is convex: the siphon perforates the septa at their centre in extremely few species, and in the rest is situated at that margin which is next the outer curve or circumference of the shell. Certain chambered shells thus characterized are straight, like the *Orthoceras*, but generally compressed, with their numerous septa joining the outer shell by foliated dentations: they are termed *Baculites*. In the true *Ammonites* the shell is discoid, and coiled upon itself as in the *Nautilus*; but it is strengthened by arched ribs and dome-shaped elevations on the convex surface, and by the tortuous windings of the foliated margin of the transverse partitions. Separate casts of the interior of the chambers are not unfrequently obtained, which have become detached by the solution of the calcareous walls and septa of the shell, or are held together by the dove-tailed lobes of the margins of the chambers.

The *Turritella* is essentially an *Ammonite* disposed in spiral coils. The *Hamites* and *Scaphites* are other modifications of the outward form of similarly-constructed chambered shells: in the former the small extremity of the shell is curved, the rest being straight; in the latter both ends are curved towards each other like those of a canoe.

With none of these species has there ever been found a trace of the ink-bag; a part, indeed, of so delicate a texture that some surprise may be excited that any evidence of its existence could be met with in a fossil state. Not only the ink-bag, but the muscular mantle, fins, and cephalic arms, of extinct Cephalopods, with chambered shells, have been discovered in Oolitic strata, which have determined such fossil shells to belong to the second and higher order of Cephalopods.³

ORDER II.—DIBRANCHIATA, Owen.

Branchiæ two, forming a pair, each with a branchial

Cephalopoda.

Cephalopoda.

heart; funnel an entire tube; mantle muscular; an ink-bag; eight non-retractile acetabuliferous arms, with two long additional tentacles in most; eyes sessile; beak horny; shell internal (save in the females of one genus).

Compared with the *Nautilus*, the cephalic organs of prehension in all Dibranchiates are much reduced in number, the external ones, continued from the oral sheath, not exceeding eight, as in figs. 97, *c*, and 100, *c*, to which, in most of the genera, is added a pair of internal and much longer tentacula, as in figs. 97 and 100, *d*. The arms are much increased in size and of a more complicated structure, supporting on their internal surface numerous suckers, and sometimes connected together by a powerful muscular web. The eyes are much larger and more complex, are no longer pendunculated, but lodged in orbits (fig. 97, *ee*). The mouth (fig. 96) is armed with two piercing and trenchant horny jaws, *c*, resembling in shape and in their vertical movements those of the *Nautilus*. The gills (fig. 95, *g*) are two in number, each with a ventricle *i* expressly appropriated to the branchial circulation; the systemic circulation having a single muscular ventricle *h*, as in the *Nautilus*. The infundibulum *b* is a complete muscular tube, shaped like an inverted funnel. They possess a gland and membranous receptacle *p* for secreting and expelling an inky fluid. The sexual organs are in distinct individuals, as in the Tetrabranchiate order. All the species of both orders of Cephalopods are aquatic and marine.

The Dibranchiate order may be subdivided into two tribes; the one provided with the eight ordinary arms and the two longer tentacles, hence called *Decapoda* (fig. 97); the other tribe without the tentacles, and called *Octopoda* (fig. 101).

The various forms of the extinct *Belemnitidae* constituted one family in the Decapod tribe. The little *Spirula*, characterized by a less complex, but internal chambered shell, is the type of a second family. The cuttle-fish (*Sepia*, fig. 97), known by its internal calcareous shell (fig. 98), which feebly represents that of the *Belemnite*, exemplifies a third family of Decapods called *Sepiadae*. The common calamary (*Loligo*), in which the internal shell is reduced to a horny quill-shaped plate, represents the fourth and most extensive family of the present tribe, which I have called *Teuthidae*; and in which one genus (*Enoploteuthis*) had the caruncle of its acetabula produced into horny claws. In all the Decapods the mantle supports a pair of fins, and the siphon is generally provided with a valve.

In the tribe *Octopoda* fins are rarely developed from the mantle; but the eight ordinary arms are longer, thicker, and are united together by a broader web, which forms a powerful organ for swimming in a retrograde direction. One family in this tribe (*Testacea*) is represented by the genus *Argonauta* (fig. 102), in which, in the female sex, the first or dorsal pair of arms is dilated at its extremity into a broad thin membrane, like the mantle in the testaceous Mollusks; by means of these membranes the animal, in fact, forms for itself an extremely light, slightly flexible, and elastic, but calcareous, symmetrical shell, which is simple, and not divided into chambers; the vacated portion communicating with the rest, and being used by the inhabitant as the receptacle for the eggs (fig. 103). The siphon is without a valve, but is articulated at its base on each side to the inner surface of the mantle. The second family of the Octopods is termed *Nuda*, the species not being provided with an external shell (fig. 101). The first pair of arms is elongated, and contracts to a point: the funnel or siphon is without an internal valve or external joints. The rudimental shell is represented by two short styles, encysted in the substance of the mantle. The typical genus of this family is termed *Octopus*, in which the

Cephalopoda.

arms are provided with a double alternate series of sessile acetabula. In a second genus, *Eledone*, the arms are provided with a single series of acetabula. In the *Sciadephorus* a pair of filaments project between each of the suckers.

The skin of the naked Cephalopod is generally thin and lubricous, and can be more easily detached from the subjacent muscles than in the inferior Mollusks. In some of the smaller Cephalopods it is semitransparent; it is densest in the Calamaries, in which the epidermal system is most developed, as is exemplified in the horny rings or hooks upon the acetabula. In the Octopods the epidermis is reflected over the interior of the acetabula without being condensed into horn. Upon the body the epiderm may generally be detached in the form of a thick white elastic semitransparent layer. The second, or pigmental layer of the skin, analogous to the *rete mucosum*, consists of numerous cells of a flattened oval or circular form, containing coloured particles suspended in a fluid. The colour is rarely the same in all the cells; the most constant kind generally corresponds more or less closely with the tint of the inky secretion. In the *Sepia* there is a second series of vesicles containing a deep yellow or brownish pigment: in the *Loligo vulgaris* there are three kinds of coloured vesicles, yellow, rose-red, and brown; in the *Octopus vulgaris* there are four kinds of vesicles, red, yellow, blue, and black. In the skin of the *Argonauta* all the colours which have been observed in other Cephalopods are present, and contained in their appropriate cells. These cells possess the power of rapid alternate contractions and expansions, by which the pigment can be driven into the deeper parts of the corium, or brought into contact with the semitransparent epiderm. If the skin of an *Octopus* be slightly touched, the colour will be accumulated, gradually or rapidly, like a cloud or a blush upon the irritated surface. The *Argonaut* strongly exemplifies this chameleon-like power of change of colour.

The sole locomotive organs in the ordinary Octopods, and the sole prehensile organs in all the Dibranchiate are the appendages developed from the head, termed "arms," "feet," and "tentacles." They have no true homology with the locomotive members of the Vertebrata, but are analogous to them, inasmuch as they relate to the locomotive and prehensile faculties of the animal.¹

The eight arms of the *Octopus* commence by a hollow cone of muscular fibres attached by a truncated apex to the anterior part of the cephalic cartilage. The fibres are for the most part oblique, and interlace with one another in a close and compact manner, as the cone advances and expands to form the cavity containing the mandibulate mouth, at the anterior extremity of which they are continued forward, and separate into eight distinct portions which form the arms. The development of the eight external arms bears an inverse proportion to that of the body; they are longest in the short round-bodied *Octopi*, and shortest in the lengthened Calamaries and Cuttle-fishes, in which the two elongated retractile tentacles are superadded by way of compensation. These latter organs are not continued from the muscular cone which corresponds with the cephalic sheath in the *Nautilus*, but arise, like the internal labial processes in that Cephalopod, close together from the cephalic cartilage, internal to the origins of the ventral pair of arms. They proceed at first outwards to a large membranous cavity situated anterior to the eyes, and emerge between the third and fourth arms on either side.

The complex mechanism of the suckers of the arms is under the most complete control of the predatory Cephalopod. Mr Broderip states, that he has attempted, with a hand-net, to catch an *Octopus* that was floating within sight

¹ Geoffroy St Hilaire regarded the cuttle-fish as a vertebrate animal bent double, with the approximated arms and legs extending forwards.

Cephalopoda.

with its long and flexible arms entwined round a fish which it was tearing to pieces with its sharp hawk's bill; the Cephalopod allowed the net to approach within a short distance of it, before it relinquished its prey, when in an instant it relaxed its thousand suckers, exploded its inky ammunition, and rapidly retreated under cover of the cloud which it had occasioned, by rapid and vigorous strokes of its circular web.

The Cephalopods which frequent the more open seas, and which have to contend with more agile and powerful fishes, have still more complicated organs of prehension. In the *Calamary* the base of the piston of the sucker is inclosed in a horny hoop with a dentated margin. In the *Onychoteuthis* the margin is produced into a long, curved, sharp-pointed claw. These formidable weapons are sometimes clustered at the expanded terminations of the tentacles (fig. 100, *f*), and in a few species are arranged in a double alternate series along the whole internal surface of the eight ordinary arms, as they were in the extinct *Belemnite*.

In connection with the uncinated acetabula at the extremities of the long tentacula of the hook-squids, may be observed a cluster of small simple unarmed suckers at the base of the expanded part. When these parts in each tentacle are applied to one another, they become locked together (fig. 100, *e*), and the united strength of both the peduncles *d* is thereby more effectually brought to bear upon any resisting object which may have been grappled by the terminal hooks. This is a very striking mechanical contrivance: human art has remotely imitated it in the fabrication of the obstetrical forceps, in which either blade can be used separately, or by the interlocking of a temporary joint be made to act in combination.

The brain (fig. 95, *a*) is inclosed in a cartilaginous cranium, together with a portion of the œsophagus, from which it is separated by the membrane analogous to the *dura mater*. Between that part of the fibrous membrane which lines the cerebral cavity and the *pia mater* covering the

in the Calamaries, but appear not to be present in the Octopods.

Cephalopoda.

From the inferior and anterior parts of the superœsophageal mass, a thick cord descends on each side of the œsophagus, unites with its fellow, and dilates below that tube to form the anterior subœsophageal ganglion, from which the nerves of the feet and tentacles arise. Two broader bands descend from the superœsophageal mass behind the preceding, and form, by a like enlargement and union, the posterior œsophageal body, which blends laterally with the anterior one, and forms with it a large mass with a central perforation. Four short and slender chords, two of which are continued from the anterior apices of the optic lobes, and two from the anterior subœsophageal lobes, converge forwards and unite to form a round flattened ganglion, which is closely applied to the back part of the fleshy mass of the mouth above the pharynx, from which are sent off the nerves to the different parts of the mouth. Two filaments from the pharyngeal ganglion descend to join a pair of ganglions below the mouth, homologous to the labial ganglions of the *Nautilus*. The nerves of the arm proceed from the anterior and inferior subœsophageal ganglion, and correspond in number to the organs which they supply, being eight in the *Octopoda*, and ten in the *Decapoda*. The nerves answering to those of the shell muscles in the *Nautilus* form a single large pair, arising from the posterior angles of the subœsophageal mass, and after a certain course outwards and backwards they expand into large stellate ganglions, from which the nerves of the mantle and of the pallial fins are derived. The branchial and visceral nerves and ganglions correspond pretty closely with those in the *Nautilus*.

With respect to the parts of the brain in the Vertebrata which are represented by the cephalic nervous masses in the Dibranchiate Cephalopods, we may regard the cordiform superior mass, which is principally in communication, and co-exists with the large and complex eyes, as the homologue of the optic lobes. The smaller superœsophageal mass, anterior to the optic lobes in the *Octopus* and some other Cephalopods, may represent an olfactory lobe. The large subœsophageal nervous mass, since it gives origin to the brachial nerves, to the acoustic and respiratory nerves, and to those two large motor-sensory columns which represent, by their structure, position, and distribution, the spinal chord of the Vertebrata, must be regarded as the representative of the medulla oblongata: it is obviously the part of the nervous centre which is most intimately connected with the vitality of the animal, and which is therefore here, as in the higher animals, the deepest seated and best protected part of the nervous system.

The Cephalopods are predatory and carnivorous animals. The curved, pointed, and trenchant mandibles (fig. 96, *c, c*), are encased upon a dense muscular cushion, *d*, and are protected by an outer lip *a*, and an inner lip *b*. The glottidium retains the true complex molluscous type (compare with fig. 29); but a greater proportion of it is uncovered by the tooth-strap, and forms soft caruncles suggestive of the pos-

session of the faculty of taste. Their retractor muscle is shown at *i*. A fin is represented as in the duct of the salivary gland. In most of the Dibranchiata a second and larger pair of salivary glands is situated on each side of the œsophagus, at the commencement of the abdominal or hepatic cavity; their ducts unite to terminate below the tongue in the concavity of the lower mandible.

The peritoneal membrane is divided and disposed as in the *Nautilus*, in order to form special receptacles for the

Fig. 95.

Plan of anatomy of Dibranchiate.

brain, there is an intervening space filled with a gelatinous arachnoid tissue. In the cuttle-fish, the superœsophageal cerebral mass *a* consists principally of a cordiform body, superficially divided into two lateral lobes by a median longitudinal furrow. From the lower and lateral parts of this body proceed the short and broad optic nerves, which constitute the peduncles of the large reniform optic ganglions, and upon each peduncle there is placed a small spherical medullary tubercle. These tubercles exist also

Cephalopoda. different viscera. The œsophagus is narrower than in the *Nautilus*, and provided with longitudinal plicæ: it dilates

Fig. 96.

soon after having passed through the cranium into a long ingluvies, forming a large cul-de-sac (fig. 95, c), at its commencement in both the *Octopus* and *Argonauta*; but in the Decapods it continues narrow and of uniform breadth to the stomach. This cavity (fig. 95, e) is an elongated sac, presenting, in the disposition of its muscular fibres, in the proximity of the cardiac and pyloric orifices, and in the thickness of the epithelial lining, the usual characters of the gizzard. The intestine, at a short distance from the pylorus, communicates with a glandular and laminated sac *q*, homologous with that in the *Nautilus*, and presenting a similar globular form in the *Rossia* and *Loligopsis*; but elongated and spirally convoluted in the *Sepia* and *Loligo*. It receives the biliary secretion between two broad lamellæ, as in the *Nautilus*. The intestine is very short in all the Dibranchiata. In the *Octopus* it is bent upon itself (fig. 95, r), as in the *Nautilus*; but in the *Sepia* and *Loligo* it is continued forwards in a straight line, as at *f* (fig. 95), from the stomach to the vent. Its internal membrane is longitudinally folded, but is smooth at the short tract beyond the entry of the duct of the ink-bag; its termination is constricted either by the muscular fibres of the branchial septum, or by those which connect together the pillars of the funnel. In the Decapods provided with fins for swimming forwards, the anus can be closed by triangular fleshy valves; and in some species these are modified into the form of antennal filaments.

The liver is of large size in the Dibranchiata (fig. 95), but of more simple form than in the *Nautilus*. In the *Sepia* it is divided into two lateral lobes, which are notched at the upper extremity; in the *Onychoteuthis* it is a simple, elongated, compressed lobe, with undivided extremities; in the *Octopus* it forms a single oval mass, flattened anteriorly; in the *Eledone* it is spherical, corresponding with the ventricose visceral sac. In the two latter genera the ink-bag (fig. 95, p) is enclosed within the capsule of the liver, and was naturally mistaken for the gall-bladder by some of the early anatomists of these Mollusca; but in the *Argonauta*, and in all the Decapoda, it manifests its distinct function by its separate position. The liver is surrounded by a smooth capsule, and is not subdivided externally into lobules, as in the *Nautilus* and lower Mollusca. The biliary ducts in the *Octopus* are simple canals, which unite and terminate by a common orifice, in the

pancreatic sac. In the *Decapoda* they receive the ducts of numerous clusters of cæcal appendages beyond the smooth part of the liver.

The ink-bag consists of tough white fibrous texture, the outer surface of which is coated by a thin silvery or nacreous layer; its inner surface presents a fine spongy glandular texture. It presents a trilobate form in the *Sepioida*, and an oblong pyriform shape in the *Sepia* and *Loligo*. It is a very active organ, and its inky secretion can be reproduced with great activity. The tint of the secretion varies in different species, as is exemplified by the Italian pigment called "sepia," and the Chinese one called "Indian ink." It is of a very indestructible nature, as is exemplified by its frequent preservation in a fossil state in both the extinct Calamaries and the Belemnites. It is affirmed by some chemists to contain a peculiar animal principle, which Vizio has termed "melanine."

Many of the Cephalopods possess the power of emitting a luminous secretion. All of them are nocturnal and social animals, and are readily attracted by bright metallic substances.

The chief modifications of the circulating and respiratory systems of the higher order of Cephalopods are expressed in the characters of the order *Dibranchiata*.

The branchiæ (fig. 95, g) are concealed, as in the *Nautilus*, by the mantle, which extends in front of the other viscera to form the branchial chamber, the infundibular muscular tube *q* projecting from its outlet. The rectum and the generative organs *o* open into the branchial chamber at the base of the funnel, manifesting the same relation of the breathing organs to the termination of the alimentary canal which characterizes the lower orders of the Mollusca. Each gill consists, as in the *Nautilus*, of a number of triangular vascular laminae, extending transversely from either side of the fleshy stem, and decreasing in size to the extremity of the gill. Each plate is composed of smaller transverse laminae, which are themselves similarly subdivided; the entire gill presenting the tripinnate structure, which affords the most extensive surface for the minute subdivision of the blood-vessels. In the *Loligopsis* each gill has twenty-four pairs of plates; in the *Sepia*, thirty-six pairs; in the *Loligo sagittata*, sixty pairs. The stem of the gill is not only attached by its base, but by a thin fibrous membrane through nearly its whole length to the mantle.

The mechanical part of the respiratory act is performed by the muscular actions of the mantle and funnel, the gills not being provided with vibratile cilia, as in many of the inferior Mollusca. The water is admitted into the branchial cavity at the anterior aperture of the mantle, outside the base of the funnel. Two large valvular folds of fibrous membrane, which are concave towards the respiratory cavity, prevent the currents from escaping by this entry. They are therefore propelled by the whole force of the contraction of the muscular mantle through the cavity of the funnel, the base of which is articulated, in most of the Cephalopods, by lateral joints, with the sides of the anterior aperture of the mantle.

In the male Cephalopod, the testis, lodged at the bottom of the visceral sac, consists of a membranous pouch, to one part of the inner surface of which are attached numerous dichotomising blind spermatid tubuli. These swell and burst at the breeding season. The spermatozoa are conveyed along a convoluted sperm-duct, where they are moulded, with added mucus, into a slender cylindrical coherent thread; this next passes into a wider tube, with glandular walls, where the thread divides into packets of spermatozoa, which become inclosed in albuminous sheaths; a glandular sac or cæcal tube (called "prostatic") communicates with the vesicular canal; and this finally opens into the pouch in which filamentary packets of sperm-material, having acquired the requisite mechanism, exhibit

Cephalopoda.

Cephalopoda.

the movements which first attracted the attention of Needham.¹

These moving filaments in the terminal pouch, or capsules of spermatozoa and sperm-fluid, with a peculiar associated mechanism, of which an internal spiral spring is the most conspicuous part, form one of the most remarkable peculiarities of the Cephalopoda, and have been regarded as parasitic worms, under the names of *Echinorhynchus*, *Scolex dibothrius*, *Needhamia expulsatoria*, &c., by different comparative physiologists. They are now denominated "spermatophora;" and they parallel in the male the albuminous packets of ova in the female. The efficient cause of their movements appears to be a combination of the contractility of the external sheath and sperm-receptacle, with the elasticity of the internal spiral membrane, and the phenomena of endosmosis. The final intention of the super-addition of protecting sheaths for the semen, like those for the ova, appears to relate to the safe conveyance of the spermatozoa to the ova of the female, there being apparently no true intromission in the Cephalopoda. The peculiar mechanism of the sperm-receptacles insures their rupture and the dispersion of their contents after their brief transit through the sea-water.

The female organs consist in the Dibranchiate Cephalopods, as in the *Nautilus*, of ovary, oviduct, and super-added nidamental glands, but with several modifications in the efferent part of the apparatus. The ovary (fig. 95, o) is always single, and the ovisacs, characterized by their elliptical form and reticulate parietes b, are attached to one part of its cavity, as in the *Nautilus*. In the cuttle-fish there is a single oviduct, with a glandular laminated outlet; and there are two distinct laminated nidamental glands on each side of its termination. In the *Octopoda* there are two oviducts, which in the *Octopus* and *Eledone* are each provided with a special glandular enlargement about the middle of their course; but there are no detached nidamental glands. In the *Loligo* there are two distinct convoluted oviducts, and two separate nidamental glands. These glands in the cuttle-fish rest upon a soft parenchymatous body, of a bright orange colour. The corresponding part is rose-coloured in the *Sepiola*; it is double in the *Rossia* and the *Calamaries*. These bodies have no ducts.

Tribe I.—DECAPODA.

Arms eight, tentacles two.

FAMILY I.—SPIRULIDÆ, Woodward.

Shell internal, nacreous, discoidal, whorls separate, many-chambered; the involute spire next the ventral surface of the body; septa concave, next the outlet; siphuncle near the concavity of the shell-curve; mantle with a tricuspid front-border, bilobed behind, and terminated by a sub-circular fleshy disc, with a narrow lamelliform appendage on each side; at the notches on the dorsal and ventral sides, above the disc, are exposed parts of the last whirl of the shell.

Genus SPIRULA, Lam.—Body oblong; arms short, with six rows of minute suckers; tentacles long, cylindrical, funnel-valved, and with elongated basal lateral joints with the mantle. The internal organization of the *Spirula* accords with the Dibranchiate type, and exhibits the modifications characterizing the Decapodous tribe, such, e. g., as the glandular follicles upon the hepatic ducts, the absence of the septum or frænum of the branchial chamber, the appendages to the branchial hearts, the absence of an

ingluvial dilatation of the gullet, the division of the liver into two lobes, and the separation of the ink-bag from the liver.

The most perfect known example of the *Spirula* is in the collection of Mr Cuming. It was picked up by Mr Percy Earl on the coast of New Zealand. This specimen is nearly three inches in length from the pallial disc to the tips of the arms; only the clavate ends of the tentacles seem to be wanting. It is figured in the *Annals and Magazine of Natural History*, vol. xv., pl. 15, and in L. Reeves' *Elements of Conchology*, part i., plate A, figs. a, b, c. The names *Spirula levis* and *Spirula australis* have been proposed for this specimen. The species *Spirula reticulata* (Owen, in the *Zoology of the Samarang, Mollusca*, pp. 14-16, pl. iv., figs. 3 and 9) is founded on a mutilated specimen, taken by Mr George Bennett, F.L.S., on the coast of Timor.

If the *Spirula* taken in the Atlantic Ocean, and figured by Péron in the *Atlas du Voyage aux Terres Australes*, tab. xxx., fig. 4, be there accurately delineated, it may be regarded as a distinct species, and retain the name of *Spirula Péronii*.

The *Spirula* is widely diffused over the warmer parts of the ocean, especially in the southern hemisphere. The delicate shell is strewn in abundance over parts of the coast of New Zealand, and a few specimens have been brought by the Gulf Stream to the south-west coast of England.

FAMILY II.—BELEMNITIDÆ, Owen, Gray.

Shell internal; the chambered and siphunculated part, called "phragmocone," is straight, conical, and is lodged in a sheath or guard, produced more or less anteriorly into a calcareo-albuminous plate, and behind into a solid "mucro," varying in length and shape. This is the part commonly known as the "belemnite." The septa of the phragmocone are concave next the outlet or base, and the siphuncle is at the ventral side. All the genera and species of the family are extinct. The acetabula of the arms were provided with horny hooks.² They range from the lias to the gault.

FAMILY III.—SEPIADÆ, Woodward.

(Cuttles or Cuttle-fishes.)

Trunk or pallial part (fig. 97, a, b) sack-shaped, bordered on each side with a narrow longitudinal musculo-dermal fin bb; shell (fig. 98) internal, gelatino-calcareous, friable, consisting of a flattened closely-laminated phragmocone bc, lodged in an open expanded guard aa, prolonged behind into a "mucro."

Genus SEPIA, Linn. (as restricted by Cuvier).—The septa of the phragmocone are very numerous and close-set; they are united by finely-undulated vertical lamellæ (fig. 98, A). The whole shell is light and porous. It is still used as "pounce," and for polishing the ivory plates of miniature-painters. It is sometimes given medicinally as an antacid, the hardening salt being pure carbonate of lime. Arms (fig. 97, c, c) with four rows of suckers; funnel valved, and articulated to two lateral tubercles on the mantle.

Sp. *Sepia officinalis*, Linn. (fig. 97).—a, constriction between "soma" and "pallium;" b, pallial fins; c, cephalic or somatal arms; d, clavate tentacles; e, eyes. The left ventral arm in the male has many of the suckers on its basal half very small or oblate; and the arm is there expanded, with the inter-acebular membrane pitted and reticulate. The spermatophora are attached *in coitu* to the lip of the female. (Steenstrup.³)

The eggs of the Cuttle-fish are of comparatively large

¹ An account of some microscopical discoveries in the Calamary, and its wonderful milk-vessels, 8vo, 1745.

² Description of certain Belemnites, preserved with a great proportion of their soft parts, &c., in the *Philosophical Transactions*, 1844. Some of the species here described have been formed into a sub-genus, called *Belemnoteuthis*; but they possess the "phragmocone" and "guard," which are the essential characters of the extinct family.

³ *Annals and Magazine of Natural History*, August 1857.

Cephalopoda.

Cephalopoda.

Fig. 97.
Sepia officinalis (one-fourth natural size).

enveloped in its proper horny covering, which is prolonged into a pedicle at one extremity, and attached thereby to some foreign body. Many of these egg-capsules are generally found clustered together. They are called "sea-grapes" by the fishermen.

Fig. 98.
Shell of *Sepia*.

FAMILY IV.—TEUTHIDÆ, Ow.
(Calamaries, Squids.)

Shell internal, reduced to an aluminous or horny plate, consisting of a stem or shaft, and two lateral expansions or wings. It is called the "gladius" or pen (fig. 99).

Sub-Family 1.—EGOPSIDÆ.¹

Eyes exposed; fins terminal and united.

Genus *OMMASTREPHE*, D'Orb. (*Flying-Squids*).—Gladius with three diverging ribs, and a hollow conical appendage; body long and cylindroid; fins terminal, large and rhombic; arms with two rows of suckers; tentacles with four terminal rows of suckers; eyes not covered by the integument. Muscular chord on the funnel.

Sp. *Ommastrephes sagittatus*

(*Loligo sagittata*, Lam.)—In the sagittated Calamary the male has a shorter body and longer and stronger arms, the second and third pairs of which have relatively larger acetabula than in the female. The spermatophora are attached in coitu, within the mantle, to its wall or to part of the viscera of the female. The species of this genus are gregarious, and frequent the open ocean. With the best organs of vision, they manifest the highest powers of locomotion in the Molluscous province, leaping out of the water so high as sometimes to fall on the decks of ships; whence they are called "flying squids." They form the chief food of the cetaceous dolphins and cachalots, and of the albatross and larger petrels. They are used as bait in the Newfoundland fisheries.

Genus *ONYCHOTEUTHIS* (*Hook-Squids*).—Gladius lanceolate, with a hollow conical stem-base; arms (fig. 100, c, c) with two rows of suckers; tentacles d long, with the clavate ends provided with a double series of

hooks f, and usually with a group of suckers at the base, which, uniting with that of the opposite tentacle, as at e, fig. 100, enables both to act in conjunction; terminal fins unite to form a rhomb.

Genus *ENOPLUTEUTHIS*, D'Orb.—Gladius and terminal fins as above; arms provided with a double series of hook-bearing pedunculate acetabula; tentacles long, with terminal hooks. The hook-squids are solitary, frequenting the open sea, often near the banks of sargasso-weed.

A specimen of the second genus (*Enoploteuthis unguiculata*) was taken during Cook's first voyage, in the South Pacific, which must have been six feet long from the tips of the arms to the end of the mantle. The huge rhomboid pair of fins are still preserved, dried, in the Hunterian Museum of the London College of Surgeons, together with spirit-preparations of sections of the uncinated arms, the heart, and the mouth. Fig. 96 is taken from the last specimen, but is reduced to one-half the natural size.

The natives of the Polynesian Islands, who dive for shell-fish, have a well-founded dread of these formidable Cephalopods.

Genus *LOLIGOPSIS*, Lam.—Arms with numerous small acetabula; the third pair usu-

Fig. 100.
Head and arms of *Onychoteuthis*.

Fig. 99.
Gladius of *Loligo*.

¹ Gr., signifying "eyes which turn."

Cephalopoda.

ally the longest, the first the shortest; tentacles very long and slender, rarely preserved in captured specimens; body conical, tapering to the extremity, at or near which is a pair of rounded fins; no infundibular valve; mantle sub-transparent, widely open anteriorly.

Sp. *Loligopsis Zygæna*.—This species has the tentacles acetabulate throughout their length. The *Loligopsis Veranyi* is remarkable for the great length of the tentacles; the suckers are limited to the clavate ends. The *Loligopsis vermicularis* has the slender head longer than the longest arm.

Genus LEACHIA, Stp.—The *Leachia Reinhardtii* is distinguished by its strong armature of cartilaginous bands on the mantle; one, denticulate, along the middle of the back; arms in length, 3, 2, 4, 1, or each with two series of suckers.

Sp. *Leachia hyperborea*, Stp.—Fins narrow, extending along half the length of the body, and forming together a lanceolate figure; arms, as to length, 3, 2, 1, 4, with very large acetabula; tentacles twice as long as the arms.

Sub-family 2.—MYOPSIDÆ.

Eyes covered (wholly or almost) by skin.

Genus CRANCHIA, Leach.—Body large, ventricose; fins small, terminal; mantle supported in front by a branchial septum; head very small; arms short, with two rows of suckers; tentacles with four rows of suckers on the clavate ends; funnel with a valve; gladius long and narrow.

The *Cranchia scabra*, Leach, a species about two inches in length, was taken off the west coast of Africa, during Tuckey's Congo expedition: the genus founded thereon was named in honour of Mr Cranch, naturalist to the expedition.

Genus LOLIGO, D'Orb. (part of the genus *Loligo* of Lamarck), (*Calamaries* or *Common Squids*).—Body elongate, especially in the male, tapering behind, with a pair of rhomboidal, terminal, more or less extended, fins; gladius narrow, pen-shaped, with the shaft produced in front—it is multiplied by age, several being found packed closely, one behind the other, in old specimens; arms with two rows of pedunculate suckers; tentacular club with four rows of suckers, the fourth left arm in the male, with the suckers of the terminal part, gradually disappearing, whilst their peduncles increase, and assume the form of long papillæ, especially along the outer margin, giving the extremity of the arm a pectinate appearance; spermatophora attached, *in coitu*, to the fringed lip of the female.

In *Loligo vulgaris* the suckers of the peduncular club are very large on the two central rows, and very small in the lateral rows; the horny ring of the central suckers is finely toothed along half its circumference.

In *Loligo Forbesii* the central rows of the peduncular suckers are scarcely larger than the lateral ones, and not more than one-third larger than the largest suckers of the third arm; the horny ring of the peduncular suckers is toothed all round. A specimen of the species has been taken which was 2 feet long, including the tentacles.

These squids are good swimmers; they also crawl, head downwards, on their cephalic disc. The ova are inclosed in long gelatinous cylindrical sheaths, and offer a close analogy to the spermatophora in the male. Bohadsch estimated a cluster of these capsules to contain nearly 40,000 eggs.

Genus SEPIOTEUTHIS, Bl. (*Long-finned Squids*).—Gladius lanceolate, narrowed anteriorly, convex dorsad; lateral pallial fins as long as the mantle.

In *Sepioteuthis sepioidea* the fourth left arm in the male has the outer row of suckers of the terminal part metamorphosed into compressed leaf-like papillæ, united by a membranous bridge with the roots of the peduncles in the opposite row, which are transformed into blunt elevations. The fourth right arm has the terminal suckers scarcely discernible, and probably assisting the left during the generative act.

The spermatophora are attached, *in coitu*, to the fringed lip

of the female (Steenstrup). The species are distributed in the Mediterranean, Indian, South Atlantic, and Australian Seas.

Genus LOLIOLUS, Stp.—Internal shell horny, broad, with the shaft sharp-keeled; no muscular chords to the funnel, and suckers without the elevated band round the horny ring, thus resembling *Sepiola* and *Rossia*.

In *Loliolus typus* the left fourth arm in the male is without a trace of sucker; the acetabular bed being converted into a compressed obtusely-dentate edge, produced by the confluent bases of the peduncles of the inner series of suckers.

Genus SEPIOLA, Leach.—Abdomen short, purse-like; fins dorsal, rounded, contracted at the base; no muscular bands to the funnel; no elevated band round the horny ring of the suckers; mantle continuous with the back of the head.

In the *Sepiola Rondeletii* the left dorsal arm in the male is expanded by the confluence of the elongated stalks of the suckers, especially of the inner row, and by a production of integument at the base of the inner side of the arm. (Stp.)

Genus ROSSIA, Ow. (so named in honour of Sir James Clark Ross, R.N., the arctic and antarctic navigator).—Body short, ventricose, with subdorsal rounded fins, no muscular bands to funnel; posterior border of the mantle free; the dorsal pair of arms in the male obliquely twisted inwards, with about eleven of the outer row of suckers elevated on long peduncles, the roots of which are compressed, leaf-shaped, and surrounded by dermal folds or processes.

"In one of my males I found two soft envelopes of spermatophora between the cutaneous folds of the arm." (Stp.)

Sp. *Rossia palpebrosa*, Ow.—This is the largest known species of the genus. It is characterized by numerous small suckers on the tentacles. A fold of integument is reflected, like a large lower eyelid in front of the eyeball. The species was obtained by Captain Sir James Ross at Elwin Bay, Prince Regent's Inlet. The utility of the peculiar defence of the eyes, in a species living in seas sometimes charged with spiculæ of ice, is obvious.

Sp. *Rossia Mölleri*, Stp.—This is distinguished by very large suckers on the tentacles, in both males and females; the middle row exceeding in size the largest brachial suckers. Hab.—Greenland.

The *Rossia dispar*, Rupp. (*Heteroteuthis*, Gray), has very large suckers on the third pair of arms.

The *Rossia Owenii*, Ball, agrees with the male, and *Rossia Jacobii*, Ball, with the female, of the *Rossia macrostoma*, of D'Orbigny, and of Forbes and Hanley.

Genus HISTIOTEUTHIS, D'Orb.—Trunk short, bursiform, with a pair of terminal subdorsal rounded fins; palpebral orifice large; first, second, and third pair of arms united by a web to within one-fourth their length from their tips.

Sp. *Histioteuthis bonelliana*, D'Orb.—This species was discovered by M. Verany in the Gulf of Genoa. The remarkable form of Cephalopod of which it is the type is beautifully figured in plates 19, 20, and 21 of the *Mollusques Méditerranéens* of that excellent Malacologist.

Section OCTOPODA, Leach.

Arms with sessile suckers, no tentacles; trunk united to the head by a broad nuchal band; branchial chamber divided by a longitudinal partition; two oviducts, without nidamental glands.

FAMILY I.—PINNATA, Owen.

A pair of advanced subdorsal fins from the mantle.

Genus SCIADOPHORUS (*Cirroteuthis*, Eschricht).—Pallial fins rounded; arms united by a web nearly to their tips; suckers in a single row, alternating with cirri. In the male a portion of the suckers seems, as it were, stripped off the lower third of the right arm.

Sp. *Sciadophorus Mölleri* (*Cirroteuthis Mölleri*, Eschricht).—Hab. coast of Greenland.

Cephalopoda.

Cephalo-
poda.

FAMILY II.—NUDA, Owen.

No pallial fins. Shell represented by two short styles in the substance.

Genus ELEDONE, Leach.—Arms with a single series of suckers. In the male the third right arm is shorter and somewhat thicker than the left one, with fewer acetabula (sixty-four instead of ninety-three in *Eledone moschata*). A strong cutaneous border commences in the middle, on the margin of the membrane, stretched between the third and fourth arms, and thence runs along the arm to its apex, where the terminal plate is furnished with several longitudinal folds. All the other arms have membranous laminae instead of suckers at their extremity. (Stp.)

The Mediterranean species, *Eledone moschata*, is so called on account of the musky odour it emits.

Genus OCTOPUS, Cuv. (Poulps).—Arms with a double alternate series of suckers united at their base by a web. The species of *Eledone* and *Octopus* were the "polypi" of Aristotle. They swim by vigorous contractions of the interbrachial muscular web, darting with the rounded end of the trunk forwards. They creep on shore with the same part upwards, and with their eight arms, like the legs of a spider, sprawling over the surface, in a rotating shuffling manner. The ink which they discharge is of a dark chestnut-brown colour. In the male the third right arm is much shorter, but is as thick or thicker than the left, with fewer acetabula, and bearing externally at its apex a longish plate provided with a greater or less number of transverse ridges with intervening pits. A muscular fold of skin connects this plate with the web at the base of the arm, the fold running down the dorsal margin of the arm; which margin is so rolled towards the inner side of the arm as to form a more or less closed channel, probably to conduct the spermatophora to the apical plate. The female oviposits on sea-weeds or in empty shells.

"*Octopi* of enormous size are occasionally met with among the islands of the Meïa-co-shimah group. I measured one, which two men were bearing on their shoulders across a pole, and found each brachium rather more than 2 feet long, giving the creature the power of exploring an area of about 12 feet without moving, taking the mouth for a central point, and the extremities of the arms, to describe the circumference." (Adams.)

Genus TREMOCTOPUS.—Dorsal pairs of arms (in the female) webbed to or near to their ends; suckers in two rows; conspicuous aquiferous pores on the back of the head.

In the male of *Tremoctopus carenae* (fig. 101) the arms are not webbed; but the third right arm *df* is enlarged with a double row of numerous (forty in each row) suckers, and a terminal disc *f*; a cavity in this arm contains a long convoluted spermatophore. It is deciduous *in coitu*, and adheres to the female, usually to the

inner side of the mantle, where it was mistaken for a parasitic worm (*Hectocotylus*, Cuvier²) when first discovered. This hectocotylised arm is further distinguished from the rest by being white or colourless.³

Cephalo-
poda.

Fig. 101.

Male *Tremoctopus*.

FAMILY III.—TESTACEA, Owen.

Dorsal arms of the female (fig. 102, 1), with much expanded terminal membranes, serving to secrete and sustain a symmetrical involuted nidamental shell. The third left arm in the male is "hectocotylised" and deciduous *in coitu*.⁴

Genus ARGONAUTA, Linn.—The characters of the family are those of its sole representative genus.

Sp. *Argonauta argo*, Linn.—On this species, which inhabits the Mediterranean, and is found in tolerable abundance at Messina and Sicily, Madame Power made her observations and experiments, which finally determined the

¹ Catalogue of Mollusca in British Museum, Part I., *Cephalopoda Antepedia*, pp. 5 and 14.

² Mémoire sur un ver parasite d'un nouveau genre (*Hectocotylus*), *Annales des Sciences*, vol. xviii., 1829.

³ Aristotle, describing this species of "Polypus," wrote, "differt mas e femina eo, quod habet corpus oblongius, et genitale, quod e piscatoribus vocatur, in brachio, album." (*Hist. Anim.*, lib. v., c. 10, 1, ed. Schneider, p. 196.)

⁴ The following is Prof. Steenstrup's summary of the sexual characters presented by the males of the *Cephalopoda*.—

OCTOPODA—		<i>Argonauta</i> <i>Tremoctopus</i> <i>Octopus</i> <i>Eledone</i>	Third { left right } arm a <i>Hectocotylus</i> , deciduous, colourless, developed in a sac. (<i>Feminae polyandrae</i>). Third right arm hectocotylised, permanently attached, coloured, developed in a free state. (<i>Feminae Monandrae</i> ?)
DECAPODA—			
<i>Myopsidae</i>	<i>Rossia</i>	First left arm hectocotylised	{ with the right one only in the middle. alone, in its whole length.
	<i>Sepioida</i>		
	<i>Sepia</i> <i>Sepioteuthis</i> <i>Loligo</i> <i>Lololus</i>	Fourth left arm hectocotylised	{ at the base. at the apex. at the apex. in its whole length.
	<i>Argopsidae</i>	<i>Ommastrephes</i> <i>Onychoteuthis</i> <i>Loligopsis</i>	no hectocotylised arm yet observed.

Cephalopoda.

long-mooted question whether that Cephalopod was the fabricator or merely the parasitic occupant of the shell.

Fig. 102.
Argonauta gondola.

The question arose out of the anomalous relations of the shell to its occupant; the shell not being attached by any muscle to the Cephalopod, and this having been observed to quit the shell and survive in captivity for some time without attempting to resume it. Madame Power first observed and published¹ the function of the brachial membranes in maintaining the shell in proper relation to the body, as shown in fig. 102, 1, where the membrane is partly retracted from the shell, which it can wholly cover. She likewise demonstrated, experimentally, the function of those membranes in the formation and reparation of the shell. She removed portions of the shell from healthy argonauts imprisoned in her aquaria, and preserved them long enough to witness the mode and degree of reproduction of the mutilated parts of the shell. She cut off one of the membranous arms, and preserved the mutilated argonaut long enough to show that the growth of the side of the shell next the amputated arm did not proceed; whilst that which remained covered by the membrane of the entire dorsal arm had received a notable increase. Specimens of the shells, showing that inequality of the two sides of the shell as the result of the experiment of removing one membranous arm, were transmitted by Madame Power to the author of the present article, by whom the experiment was suggested to that lady.²

The argonaut shell is, however, peculiar to the female sex. It has the special function of an incubating and protective nest. It is not the homologue of the camerated shell of other testaceous Cephalopods, nor of the internal rudimental shell in naked Cephalopods. It is to be regarded as answering to the cocoon which is secreted for a similar office by the leach and in many Articulata, and to the nidamental float in *Janthina*.

Fig. 103 shows the place of attachment of the eggs, which are appended by filamentary stalks to the involuted spire of the shell. They are usually compacted in that part of the shell, and concealed by the body of the parent

argonaut. This figure, and fig. 102, are of the species described by Mr Adams³ as the *Argonauta gondola*, of

Cephalopoda.

Fig. 103.

Nidamental shell and eggs (*Argonauta gondola*). is more ovoid and elongated; the head is narrower; the funnel broader, shorter, and furnished, at the upper and anterior extremity, with two conical elongations; the eyes are considerably larger and slightly more prominent; the tentacular arms are much shorter in comparison and of greater width, more particularly at their basal portions; the suckers are much larger, more prominent, and placed closer together. This species varies also considerably in colour from *A. argo*. The extremities of the brachia are marbled with deep-red brown, and, in the other parts, are covered with large, irregular, oval, reddish blotches, each margined with a dark colour; the circumference of the suckers is marked with brown spots; the upper surface of the funnel is covered with pale pink, rather scattered and irregular, quadrate blotches, margined with dark-red brown; the mantle, on the dorsal surface, is densely sprinkled with round and square spots of a chestnut-brown and crimson of different sizes; the velamenta are minutely dotted with crimson and red-brown, and have a more bluish tinge than those of *A. argo*; the under surface is mottled and minutely dotted with dark chocolate on the arms, and on the body is marked with small, irregular, dark red-brown spots.

"In the specimen of *A. gondola* from which the accompanying drawing was made, the ovary was distended with ova, but in a much less advanced stage of development than those deposited in the shelly nidus. Some of these latter were sufficiently matured to enable me to trace, under the microscope, the early indications of the being of the argonaut; and although the progress is not followed very far, it is sufficient to ascertain the similarity with the changes observed by Poli in the same genus, with whose writings I afterwards compared my remarks; the only difference of any importance appears to be that Poli regarded as the shell what I have called the yolk-bag. At first, the ova are semi-opaque, pale yellow, and apparently speckled minutely, which is owing to the granular yolk; afterwards they become clouded with light brown blotches, and three dark spots make their appearance, one for each eye and one for the viscera; these spots, in the next stage, approach each other, and a faint outline of the future argonaut is visible, a club-shaped embryo, rounded in front and tapering behind. The front part is then lobed; a black mark for the horny mandibles is perceived, and the eyes are large and prominent; the yolk-bag, or vitellus, is next seen very distinctly, and the processes extending from the head are more elongated." (*Loc. cit.*, p. 7.)

The most complete series of observations on Cephalopodous development are those recorded by Kölliker, of the cuttle-fish (*Sepia officinalis*).¹ The primary germ-cell

¹ *Giornale di Gabinetto di Messina*, December 1834; and *Ragguaglio delle Osservazioni ed Esperienze fatte sullo Argonauta Argo* (L.) da Madama Jannette Power, in *Giornale di Scienze, Lettere ed Arti*, Messina, Maggio, 1836. See also *Proceedings of the Zoological Society of London* for February 1839.

² *Reports of the British Association*, 1844, Transactions of the Sections, p. 74. The fabled office of the brachial membranes, as "sails" to waft the argonaut along the surface of the ocean, and that of the attenuated arms, as "oars" extending over the sides of the boat, have afforded a favourite topic for poetic imagery and philosophic analogy during many ages; and the little hypothetical navigator of nature's ship has been the object of the disquisitions of the naturalist from Aristotle to Cuvier, and of the song of the poet from Callimachus to Byron.

³ *Zoology of the Samarang*, Mollusca, p. 3.

Cephalopoda.

divides and subdivides, but assimilates only a small proportion of the vitellus to form the germ-mass; the rest of the yolk being taken in for food after development of the embryo, as in the oviparous shark and bird. What is called a "germinal area" is thus formed upon the yolk. The basis of the trunk or mantle seems to be the first to appear; but almost simultaneously follow parts which are afterwards recognised as the "funnel-lobes," "gills," and "eyes." Next appear parts of the head called "anterior" and "posterior" cephalic lobes; then the arms, beginning by the ventral pair, and all these parts, save the gill-rudiments, manifest ciliary action. The lobes or crura of the funnel elongate, the eyes become reniform, the mouth is established as a median semilunar depression with a raised border. The mantle first liberates a border at its ventral side (some Cephalopods, *e.g.*, *Sepioida octopus*, retain this stage); afterwards the free border extends all round, and by its growth begins to cover the gills. The crura of the funnel approximate, the cephalic lobes coalesce, the bases of the dorsal pair of arms extend, approximate, and complete the encompassing of the mouth. There is nothing in the developmental relations of the cephalic arms that countenances the idea of their homology with the repent ventral disc of Gastropods. The crura of the funnel first coalesce at their dorsal margin, and in *Nautilus* the development of the tube is arrested at this stage; but the ventral overlapping borders of the funnel-lobes next coalesce, completing the tube. The alimentary canal, with the liver and ink-bag, are successively developed. The molluscous bend of the intestine is formed as the mantle-cavity rises from the germinal area; the anus having been previously established between the gill-rudiments and the ventral ends of the funnel-lobes. The vitelline sac is drawn in between the mouth and vent, and becomes divided into an internal and external yolk; the latter becoming progressively "internal" until finally absorbed. At a certain stage of pallial growth alternate contractions and expansions of the mantle indicate the respiratory movements. The ink-bag is conspicuous by the colour of its contents, which suffice to blacken a considerable quantity of water. At the period of exclusion five layers of the shell of the young cuttle-fish have been formed; but, except the nucleus, which is calcified, they are flexible and transparent; the internal shell of the *Teuthidæ* is arrested at this stage. The pallial fins are relatively broader than in the mature animal, and the cephalic arms are furnished with both suckers and a basal web. Thus the little cuttle is enabled to swim either backwards or forwards, and its eyes have acquired the requisite development to direct it to its appropriate food, or warn it of an approaching enemy, from which it has also the means of concealing itself by its already developed ink-bag.

In the class at the summit of the Molluscous series, as in the *Arachnida* of the Articulate series, there is no metamorphosis. The Cephalopodic character is manifested before the parts of the embryo are completed; even the Dibranchiate peculiarity of the infundibular cartilages is recognisable, when as yet, only the visceral sac, funnel, gills, and eyes have been outlined on the germ-mass. No phase or form of Molluscous existence below the Cephalopod is transitorily manifested. Before the ciliary action is visible on the germ-mass, the parts that afterwards exhibit it bear the Cephalopodous stamp. The retained conditions which are transitional in the embryo *Sepia* are peculiar, as has been pointed out, to certain other Cephalopods. Were growth superinduced at any arrested stage of Cephalopodous development, no known inferior form of Mollusk would result; and no arrested stage of Vertebrate development would produce anything like a cuttle-fish.

Cephalopoda.

The notices of the habitats of the species selected to illustrate the several divisions of the Molluscous province, will have served to convey a general idea of their distribution in space. It remains only to sum up briefly the relations of the Mollusca to time.

In the oldest known fossiliferous deposits—Cambrian or Lower Silurian—this province of life is represented by species of BRACHIOPODA (*Orthisina*, *Pseudocrania*), of LAMELLIBRANCHIATA (*Lyrodesma*, *Modiolopsis*), of GASTEROPODA, both Nucleobranchiate (*Maclurea*, *Belerophon*) and Scutibranchiate (*Rhaphistoma*, *Holopæa*), and of Tetrabranchiate CEPHALOPODA (*Gonioceras*, *Lituites*, *Endoceras*). Thus the leading modifications or classes of the MOLLUSCA appear simultaneously at the earliest beginnings of life to which our present knowledge reaches. Some additional but allied species of the same families appear in the Upper Silurian beds. In the Devonian system of rocks the BRACHIOPODA are principally represented by *Spirifera*, and *Producta* here makes its first appearance; the LAMELLIBRANCHIATA are exemplified by *Megalodon* and *Pterinea*; the CEPHALOPODA by *Clymenia* and *Bac-trites*. The *Goniatites*, which make their first appearance in the Devonian, flourish most in the Carboniferous series. New BRACHIOPODA—*e.g.*, *Camarophoria*—first appear in the Permian, at which period the Lamellibranchiate *Myalina* was most abundant. A Permian Bivalve has been referred to the genus *Lima*; the Brachiopodous *Lingula* and *Crania* have continued to be represented from the Cambrian epoch to the present day; but most of the Molluscous genera of the Palæozoic rocks are extinct.

True Ammonites first appear in the Trias, and the Tetrabranchiate Cephalopods were most abundant and various at the Oolitic periods, when the Dibranchiates, under the form of Belemnites, first appeared on the stage of life. In the same secondary strata the GASTEROPODA are chiefly represented by asiphonate genera. The siphonated *Aporrhais* and *Pyrula* first appear in the Cretaceous strata. Fresh-water *Pulmonifera* occur in the Purbeck beds; but terrestrial species have not been found in strata older than the Tertiary. The Lamellibranchiate genera are reckoned by Woodward to be seven times more numerous in the newer Tertiary than in the Palæozoic strata. In the latter the genera belong to the families with an open mantle. "The siphonated Bivalves do not appear till the middle of the secondary age, and are only now at their maximum." (*Manual*, p. 418.) Fossil shells have afforded the readiest mode of testing and characterizing the chief divisions of the Tertiary system. To those strata in which a small per-centage is only referable to recent species the term "Eocene" is given, as if the dawn of actual life had then appeared. Strata of the "Miocene" age are those that have not more than 50 per cent. of recent species. When they constitute from 50 to 70 or 80 per cent. they characterize the "Pliocene" Tertiary beds.

The natural families of the MOLLUSCA which seem now to be verging towards extinction are the *Rhynchonellidæ*, the *Trigoniadæ*, and the *Nautilidæ*. The following seven families have altogether passed away:—*Productidæ*, *Orthisidæ*, *Spiriferidæ*, *Hippuritidæ*, *Orthoceratidæ*, *Ammonitidæ*, and *Belemnitidæ*.

In this retrospect of Molluscous organization, so far as it can be carried through the dark vistas of geological time, we discern "an ascent and progress in the main." Lamellibranchiate have superseded Palliobranchiate Bivalves; Siphonate have succeeded Asiphonate Univalves; and the Dibranchiate now vastly outnumber the Tetrabranchiate Cephalopods. (R. O.)

² *Ibid.*, taf. ii., fig. xvi.

Moloch
||
Molton.

MOLOCH, or **MOLECH**, or **MILCHÔM**, the national god of the Ammonites, who dedicated their children to him, by making them "pass through the fire." There are various opinions concerning this method of consecration. Some think that the children leaped over a fire sacred to Moloch; others are of opinion that they passed between two fires; and others conceive that they were really burned in the fire by way of sacrifice to this god. That the latter opinion is the only tenable one may be shown from such passages as Ps. cvi. 38; Jer. vii. 31; Ezek. xvi. 20, xxiii. 37. It cannot be precisely ascertained at what period the Israelites became acquainted with this idolatry, but it is highly probable that it was before the time of Solomon, the date usually assigned for its introduction.

Moses in several places forbids the Israelites to dedicate their children to this god, as the Ammonites did, and threatens death and utter extirpation to such persons as should commit this abominable idolatry. (Lev. xx. 1-5.) There is great probability that the Hebrews were much addicted to the worship of this deity; since Amos (v. 26), and after him Stephen (Acts vii. 43), reproaches them with having carried along with them into the wilderness the tabernacle of their god Moloch.

Solomon built a temple to Moloch upon Mount Olivet (1 Kings xi. 7); and Manasseh, long afterwards, imitated his impiety by making his son pass through the fire in honour of Moloch. It was chiefly in the valley of Tophet and Hinnom, to the east of Jerusalem, that the Israelites paid their idolatrous worship to this false god of the Ammonites. After the restoration all traces of this idolatry disappear.

The accounts of this idol and his worship found in the Old Testament are very scanty. Münter has collected the testimonies of the classical writers on this point with great completeness, in his *Religion der Karthager*. Many of these notices, however, only describe late developments of the primitive rites; the description, *e. g.*, of the image of Moloch as a brazen statue, which was heated red hot, and in the outstretched arms of which the child was laid, so that it fell down into the flaming furnace beneath. This account, which is first found in Diodorus Siculus as referring to the Carthaginian *Kρόνος*, was subsequently adopted by Jarchi and others, but is not admitted by Movers, to apply to the Moloch of the Old Testament.

The names of Moloch ("king") and Baal ("lord") are almost synonymous. Their connection is seen by comparing Jer. xxxii. 35 with xix. 5; where both names are used as if they were interchangeable, and where human sacrifices are ascribed to both deities. Baal is the chief name by which the principal god of the Phœnicians is known in the Old Testament; but only the two above-cited passages ascribe to him the sacrifice of human victims. The Greek, and Latin authors, however, give abundant testimony to the human sacrifices which the Phœnicians and their colonies offered to their principal god, in whom these classical writers have almost always recognised their own *Kρόνος* and Saturn. Thus we are brought to the difficulty of reconciling Moloch, as Saturn, with Baal, as the sun and Jupiter. In reality, however, this difficulty is in part created by our association of classical with Semitic mythology. When regarded apart from such foreign affinities, Moloch and Baal may appear as the personifications of the two powers which give and destroy life, which early religions regarded as not incompatible phases of the same one God of nature.

MOLTON, **SOUTH**, an old market-town and municipal borough of England, county of Devon, on the right bank of the Mole, 26 miles N.N.W. of Exeter. It has an ample market-place and several well-built and cleanly-kept streets. The principal building is the parish church, a Gothic edifice of the fifteenth century, containing a richly-carved

stone pulpit. It has also a guildhall and a borough jail. Manufactures of coarse woollen fabrics and lace are carried on here. The borough is governed by a mayor, 3 aldermen, and 12 councillors. Market on Saturday. Pop. (1851) 4482. In the neighbourhood are some rich copper mines, where gold is occasionally found. About 3 miles to the N.E. is a small village called North Molton.

MOLUCCAS, or **SPICE ISLANDS**, a numerous group of islands in the Asiatic Archipelago, situated between Celebes on the W. and New Guinea on the E., and stretching from N. Lat. 2. to S. Lat. 9. They are believed to amount to several hundreds, though many of them are small and uninhabited. The group is formed of three smaller clusters, viz., the Gilolos or Moluccas proper, the Ceram group, and the Timor Laut group. The first of these, extending from 2. S. to 3. N. Lat., comprehends the islands of Gilolo, Morty, Mandioly, Batchian, Ooby, Mysole, Ternate, and Tidore, besides others of smaller size. The cluster of Ceram, which lies in the centre of the group, between 3. and 5. S. Lat., contains, among others, the islands of Ceram, Booroo, Amboyna, and Banda. The third group lies farther to the S., situated between Australia and the W. of New Guinea, and includes the Timor Laut, the Key, and Aroo islands. The surface of the whole group is decidedly mountainous, and attains in some of the islands heights varying from 7000 to 8000 feet above sea-level. In its geological structure the group is principally volcanic, and contains several active craters, as well as a number of hot springs, which are found chiefly in the island of Amboyna. The outline of the mountains, moreover, is bold and rugged, and the coasts are both steep and irregular. Violent earthquakes are of frequent occurrence. The mountains are extensively wooded, even to their summits; while in the lower regions there is a rich soil. There are numerous excellent harbours, but sand-banks are frequently thrown up on the coast by the earthquakes, which render the navigation intricate. Owing to their tropical situation, the climate of the Moluccas is at all seasons warm; but the smallness of their size, and the prevalence of the monsoons, prevent the heat from rising to an excessive degree. From October or November till April or May, when the N.W. monsoon prevails, the hot and rainy season continues; but during the other months, when the S.E. monsoon blows, the temperature is considerably lower. The moisture of the air, however, is at all times great, and even during the dry season occasional showers fall. The nature of the climate and soil prevent the cultivation of corn in the Moluccas; and the principal food of the natives is obtained from the sago palm; besides which, bread-fruit, cocoa-nuts, and many other products of tropical countries, grow in great abundance. Spices, however, as the name of the islands indicates, are the articles of produce most important to Europeans. Of these, cloves and nutmegs are the principal, and are exported in large quantities. Sandal and other kinds of wood useful for furniture are also obtained here. Small quantities of gold, coral, madrepore, and mother-of-pearl are found on the islands; and some commerce is carried on with China in edible birds' nests, sea-slugs, and sharks' fins. The Dutch monopolies, however, which have trammelled the trade here for so many years, are now almost completely abolished, and the good effects are rapidly becoming more apparent in an extended commerce. The inhabitants of the Moluccas are of two races, —the Papuans and the Malays. The former, believed to be the same as the inhabitants of Australia, have in many of the smaller islands been exterminated by the Malays, and in the larger ones have only retained possession of the interior and mountainous parts. The Moluccas were first visited by the Portuguese in 1510; but shortly after, their right of possession was disputed by the Spaniards under Magelhaens, at the head of a small fleet sent out by Charles

Moluccas.

Molyn. V. This dispute at length terminated in favour of the latter. It was not till 1596 that the Dutch made any permanent settlements on these islands. The Dutch East India Company, founded in 1603, had obtained in 1618 the supremacy over many of the princes of the Moluccas, who were allowed to retain their authority subject to the company. This company was dissolved in 1795, and the Moluccas became immediate dependencies of Holland. During the French war of 1796, however, they were taken by the British, who held possession of them till 1800, when they were returned to Holland. The islands were again occupied by the British in 1810, but were finally restored to the Dutch in 1814, by the treaty of Paris.

MOLYN, PETER, surnamed *Il Tempesta* and *Pietro Mulier* or *De Mulieribus*, a distinguished painter, was the son of an artist of the same name, and was born at Haerlem in 1637. At an early age he was initiated in his art by his father, and is said to have been so fond of drawing, that he used to play truant from school, and to skulk by the sea-shore, sketching the ships in the distance, and the cattle that were grazing near him. His first models were the hunting pieces of Snyders; and his imitations, if continued, might in course of time have rivalled their originals. In his thirtieth year he was converted to Popery by a Carmelite monk, and shortly afterwards proceeded to Rome. There Molyn practised his art with great success. The Duke of Bracciano became his patron, and his fame rapidly increased. He was especially remarkable for the wild imaginative power with which he represented devoted ships tossing amid the confused turmoil of the elements. So striking, indeed, was his success in storm scenes, that he came to be generally known among the Italians by the name of "Tempesta." He also excelled in landscape-painting. His pictures of that description are marked by an imposing variety of scenery, consisting of woods, lakes, rocks, and romantic edifices, overhung by troubled skies, and relieved by lively and expressive figures. While Molyn was thus raising himself in the rank of his profession, he was also degrading himself in the scale of morality, and was fast becoming insensible to every virtuous emotion. At length, it is said, growing tired of his wife, an Italian lady, he left Rome on some pretence, and, after visiting Venice and Milan, settled in Genoa. From this city he was not long in despatching an accomplice to Rome with a letter to his wife charging her to come to him with the messenger. The lady, full of suspicion, at first refused, but on a second summons complied. She was murdered on the way by her companion; and her husband at the same time married a woman of Genoa, of whom he had become enamoured. Such suspicious circumstances led Molyn to be tried for murder, convicted, and condemned to perpetual imprisonment. The gloom of his dungeon, and the terrors of his guilty conscience, seem to have stimulated the peculiar powers of his imagination, for the tempests which he continued to paint were darker and more terrific than before. After Molyn had lain in prison for five years, according to some, or for sixteen years, according to others, he contrived to escape. Taking up his abode at Milan, he plied his pencil with greater success than ever, and increased both in affluence and in profligacy. He lived most sumptuously, and kept a private menagerie to afford him facility for the study of animal-painting. At the same time he became so notorious a libertine that he received the additional surname of "Mulier." Towards the close of his life the decaying faculties of Molyn failed to sustain him in his former style of living, and he lapsed into comparative poverty. He died of a fever in 1701. Many of his pictures may be seen among the collections in Milan and in its neighbourhood. (See Lanzi's *History of Painting*, and Stanley's *Dutch and Flemish Painters*.)

MOLYNEUX, WILLIAM, a learned mathematician, was descended from a family of fortune, and was born at Dublin in April 1656. He entered the university of his native city in 1671, and after graduating as B.A., he repaired to London in 1675 to study law at the Middle Temple. The greater part of his time, however, was devoted to philosophy and mathematics. On his return to Ireland in 1678, his independent fortune enabled him to marry, and to devote all his time to the cultivation and advancement of his favourite studies. It was at his suggestion that the Dublin Philosophical Society was instituted in 1683. He became its first secretary; and by the zeal and talent with which he discharged this office, he speedily attracted the notice of some of the most influential men in the country. The consequence was, that in 1685 he was appointed by the Irish government to inspect the fortresses in Flanders; and in the following year he was elected a member of the Royal Society of London. During the commotions that prevailed in Ireland in 1689 and 1690, Molyneux was in England engaged in completing his principal work, the treatise on Optics. In 1692 it was published in 4to at London, under the title of *Dioptrica Nova*, and with an appendix containing the theorem, newly discovered by Dr Halley, for finding the foci of optic glasses. Molyneux sat in the Irish Parliament in 1692 for the city, and in 1695 for the university of Dublin. He was a bosom friend of Locke, and while suffering under his last illness, he undertook a journey to England to visit that philosopher. His death took place in October 1698. Molyneux also wrote a *Translation of the Six Metaphysical Meditations of Descartes*, together with the objections against them by Thomas Hobbes, Lond., 1680, and twenty-seven papers on miscellaneous subjects in the *Philosophical Transactions*.

MOMBAS, a seaport-town of Africa, on a small island, 3 miles in length by 2 in breadth, in a bay on the coast of Zanzibar, in Lat. 4. 4. S., Long. 39. 38. E. The bay in which the island is situated is about 5 miles in length by 3 in breadth, and forms the harbour of Mombas, said to be one of the best in the world. The coasts of the island consist of steep cliffs of madrepore, and render the town almost impregnable; while it is still further defended by an old Portuguese fort, situated on an elevation to the S. of the town. The town, which is in a wretched and ruinous condition, consists of two parts,—one occupied by Arabs, the other by Sowhylese, a Moorish race, who inhabit a great part of this coast. Although Mombas is very suitable both as a commercial and military station, it seems to be less used in the former capacity than Uzi, a town which absorbs most of the trade of the neighbourhood. Mombas was first visited by the Portuguese under Vasco de Gama in 1498, and the town was then large and flourishing. In 1505 Francisco de Almeida, the Portuguese viceroy of India, in revenge for some insults offered by the inhabitants, took and burned the town. It was, however, afterwards rebuilt, when the Portuguese in 1529 returned and repeated their work of destruction. From that date to 1720 it was held by the Portuguese. In the latter year Mombas fell into the hands of the Imam of Muscat, but he was soon dispossessed by a rebellion of the inhabitants. From 1824 to 1826 the town came under British protection; but it is now governed by an Arab sheikh. Pop. 3000 or 4000.

MOMPOX, a river-port town of New Granada, capital of a province of the same name, in the department of Magdalena. It is situated on the left bank of the Magdalena River, about 20 miles above its confluence with the Cauca. Lat. 9. 15. N., Long. 74. 30. W. The town is regularly laid out, with broad streets crossing each other at right angles. Some of the houses near the centre of the town are well built; but the greater part of them are little more than mere sheds. Mompox has a handsome custom-house, and a quay sufficiently elevated above the

Molyneux

ism.

stream to be secure from the great floods, which in the month of December raise the waters of the river 10 or 12 feet above their usual level. This town is of considerable importance, being the great commercial emporium for the Magdalena valley. The climate is very warm and moist; and the neighbourhood is infested with alligators and mosquitos. Pop. (1851) 11,600.

MOMUS, in fabulous history, was the god of raillery, or the jester of the celestial assembly, who ridiculed both gods and men. He is the personification of mockery and censure. Being chosen by Vulcan, Neptune, and Minerva, to give his judgment concerning their works, he blamed them all: Neptune for not making his bull with horns before his eyes, in order that he might give a surer blow; Minerva for building a house which could not be removed in case of bad neighbours; and Vulcan for making a man without a window in his breast, that his secret thoughts might be seen. Venus he considered alone blameless. For the freedom of his reflections upon the gods, Momus was expelled from heaven. He is generally represented as raising a mask from his face, and holding a small figure in his hand.

MONACHISM (from Latin *monachus*, a monk; Greek *μοναχὸς*, solitary) is a general name descriptive of a mode of religious life which has prevailed in the church from almost the earliest ages, and which, during many periods of its history, has formed the most characteristic and powerful expression of its activity. It sprang into settled existence during the third century, and was the natural product of many influences then moving the church. Previously to this period, indeed, a system of solitary and ascetic devotion is found prevailing among the Jews both in Palestine and in Alexandria. The Essenes, on the western shores of the Dead Sea, and the Therapeutæ, on the borders of Lake Moëris, seem to have formed regular communities of ascetics, whose existence long preceded the rise of Christian Monachism, and to whose example the origin of the latter may in some degree be attributed. The main causes out of which Monachism arose, however, are undoubtedly to be found within the church itself,—in those hardships and persecutions which oppressed it, especially during that age, and the spirit which these persecutions naturally quickened and fostered. During the severities which followed the edict of Decius in the year 250, many Christians were driven from their homes in search of shelter from the relentless vengeance which pursued them. The comparative security of those remote wilds in which they sought refuge, the peacefulness and freedom from idolatrous intrusion in which they found themselves, combined with a growing spirit of mystical devotion which had sprung up, as in many other cases, from the very extremity of the social distractions in the midst of which they had lived, seem to have been the direct sources of the monastic idea. Such an isolation as that in which many now found themselves came to be regarded by them, under the force of such circumstances as those in which they were placed, as the only possible realization of the Christian life. In such a position alone did it appear practicable to carry out that spirit of self-denial and abstinence from worldly enjoyments which represented the ideal of their holy calling.

Egypt was the fruitful soil in which such thoughts germinated and sprung to maturity. The honour of their original has been shared by two names—Basil and Anthony; the former of whom may be regarded as the first in point of time who exemplified in his own practice that Christian asceticism which developed into Monachism; but the latter of whom was really the first who drew such attention to the monastic life as to spread abroad its fame and attract many to its adoption.

Anthony was born on the borders of Upper Egypt, in the village of Coma, in the province of Heracleopolis, about the

year 251. A spirit of simple and earnest, but somewhat unintelligent piety, animated him from his youth. Losing both his parents about his twentieth year, the care of a young sister and of considerable property devolved upon him. Setting aside the ordinary Christian obligations arising out of this position, he conceived himself called upon, like the rich young man in the Gospels, to dispose of his property, and submit to a life of voluntary poverty, in which he might, without impediment, give himself to his spiritual duties. In obedience to this impulse, he assigned his landed estates to the inhabitants of his native village, under condition that he should receive no trouble as to any charges to which they were liable; and having made provision for the education of his sister with a society of pious virgins, he settled down near his paternal mansion, and commenced a life of rigid asceticism. He supported himself by the labour of his hands, and distributed whatever exceeded the supply of his own bare wants for the benefit of the poor. This solitary life, however, was not without its temptations. Those natural feelings which he strove to mortify continued to assert themselves in such a manner as to disturb the serenity of his spiritual contemplations, and grosser feelings even obtruded themselves under the guise of alluring imaginations, which rose before him with a more painful distinctness the more he laboured to subdue them. Afterwards he learned the more Christian way of resisting such temptations by cheerful activity and trust in the presence of the Lord; but at first he thought to overcome them by a still stricter seclusion and more severe regimen. He retired to a farther distance from his native village, and took up his abode in a recess of rock, such as the Egyptians used for purposes of entombment. Here he fasted and afflicted himself till he was overtaken by illness, and carried back in a fainting and semi-deranged condition to the village. A morbid spirit of devotion, however, burned in him too ardently to be quenched. He afterwards sought a still more distant retirement, where he remained for twenty years, maturing a saintly renown which spread abroad his name, and brought many to seek his advice and to settle under his encouragement to the same mode of life. The deserts of Egypt began to swarm with devotees, who courted his presence and example, and naturally acknowledged him as their leader. The love of seclusion prevailed over his love of power; and the numbers who intruded upon his solitude drove him to a still more inaccessible retreat among the mountains. But even here he did not escape molestation. Followers gathered around him in spite of all his efforts to maintain his privacy; and the first rudiments of a monastery grew up in this remote wild. Anthony did not indeed aim at any complete organization of his followers; this task remained for another; but he taught them to labour for their support, and directed to some extent their religious duties.

The life of Anthony was prolonged to upwards of a hundred years, and his saintly fame, as may be easily conceived, grew with his years, till a peculiar sacredness and a miraculous virtue were supposed to attach to his person. On two occasions on which he made his appearance in Alexandria the religious enthusiasm which he excited was intense and universal; and especially on the latter occasion, in the year 352, when he was more than a hundred years old, it reached such a height that even pagans are said to have pressed forward to touch his garment, in the hope of being healed of their diseases. He distinguished himself at such times of public activity as the warm friend of Athanasius in his contest with Arianism; and it is to this circumstance that we probably owe the record of his life from the pen of the great Trinitarian—a record to which the historian is indebted for such facts as we have now related.

The system thus begun by Anthony speedily spread into

Monach-
ism.

Monach-
ism.

Syria and Palestine, favoured by the congenial circumstances of climate and the prevalence of a similar ascetic spirit to that which existed in Egypt. Hilarion, a disciple of Anthony, was chiefly instrumental in the promotion of Monachism in Palestine; while the great Basil of Cæsarea, the fellow-student and friend of Gregory Nazianzen, warmly embraced its spirit, and more than any other contributed to its progress throughout Syria and to the shores of the Black Sea. It is interesting to contemplate in such men as Basil and Gregory, particularly in the latter, the struggles of the monastic with the higher and more comprehensive Christian spirit, and the manner in which this spirit at length succumbed to the perverted tendency of their age, always gathering fresh strength from the increase of social confusion and disorder. Gregory, indeed, never virtually assumed, like Basil, the monastic vows; but the triumph of the ascetical bent was in the end scarcely less complete in him than in his friend. It is deserving of notice that the single monastic order which has subsisted in the Greek church derives its name from St Basil.

While the institution of Monachism thus extended itself, from the example of Anthony, not only in Egypt, but throughout the East, its more complete organization is associated with the name of Pachomius, another Egyptian ascetic, who, independently of Anthony, had entered on a similar career. To him is attributed the foundation of the cloister life, or the collection of the monks in several classes, according to a regular system, and in one large connected building. This was properly the first establishment of the *monastery* or *cænobium*. The whole community of monks thus formed was placed under a president or *abbot* (from the Hebrew or Syriac word for father), from whom descended an organized gradation of offices and ranks, fitted to preserve the integrity of the society and to secure its order. In the natural course of things, this organized form of Monachism soon came to usurp an exclusive character as the only valid expression of the ascetic spirit. The earlier Anachorets—who lived in single cells, with only a casual combination, and without submitting to any definite rule—were gradually absorbed into the more regular establishments, although in the East they long continued to survive, and to assert their independence in all shapes of ungoverned fanaticism. One class of these independent ascetics, who are known to us under the name of Sarabaites, seem to have been peculiarly obnoxious to the regular monks in the vigour with which they maintained their separate position, and refused to own any government or superior. Cassian, a monk of Palestine, who travelled into Egypt towards the close of the fourth century, with the view of inquiring into the various orders of ascetics there, attributes to the Sarabaites all sorts of excesses and disorders; but his picture is to be received with suspicion, as that of a partizan who resented their independence as insubordination, and blackened their characters because they opposed his system.

The most various results, as may be imagined, sprang from an institution like eastern Monachism. In some cases there was formed a comparatively pure spirit of devotion, such as that which, upon the whole, with all his earlier excesses, animated its great founder Anthony. Nor can it be disputed, that social consequences of a useful and beneficent kind followed the establishment of monasteries throughout the deserts of Egypt and along the bleak shores of the Pontus. A ready and generous hospitality distinguished the cloisters. The traveller received with an ungrudging spirit maintenance and lodgings. The Cœnobites of Egypt, especially, were productive corn-growers, and sent ships laden with food and articles of clothing to be distributed among the poor of Alexandria. The wildest and most ridiculous excesses at the same time grew out of

Monach-
ism.

the system. Bands of roving devotees, historically known under different names, as *Euchites* (εύχεται), from their notion about constant inward prayer, as *Choreutes* (χορευται) from their mystic dances, and as Enthusiasts (εὐθυσιασται) from their pretended spiritual communications, infested whole districts of country, and spread themselves from the Nile to the Black Sea. These fanatics abandoned all useful employment, and even any regular practices of devotion, and professed to give themselves up to spiritual contemplation; not unfrequently degenerating, by that necessary reaction inherent in all extremes, into gross licentiousness. Individual fanaticism, moreover, took the most grotesque and incredible shapes; as in the case of the famous Simeon Stylites, who is reported to have passed thirty years on the top of a pillar 60 feet from the ground. "Habit and exercise," writes Gibbon in his characteristic manner, "instructed him to maintain his dangerous position without fear or giddiness, and successively to assume the different postures of devotion. He sometimes prayed in an erect attitude, with his outstretched arms in the figure of a cross; but his most familiar practice was that of bending his meagre skeleton from the forehead to the feet; and a curious spectator, after numbering twelve hundred and forty-four repetitions, at length desisted from the endless account. The progress of an ulcer in the thigh might shorten, but it could not disturb, this celestial life; and the patient hermit expired without descending from his column." (Milman's *Gibbon*, vol. vi., pp. 251-2.)

Athanasius has obtained the reputation of extending Monachism into the West. During his compulsory sojourn in Rome in 341 he is said to have carried certain Egyptian monks in his train, whose austerities and devotion, though at first disgusting to the polished Romans, gradually attracted interest, and at length admiration. His *Life of Anthony*, moreover, which was speedily translated into Latin, gave a great impulse to the monastic spirit. It could not fail, indeed, that this spirit, so soon as it became dominant in the East, should spread to Rome, and, in such a centre of mingling superstitions, receive a ready support. All the most illustrious of the western teachers contributed by their countenance to this result. Ambrose of Milan, Martin of Tours, and even Augustine, were drawn within its influence, and lent it their encouragement. The restless activity of Jerome during his residence in Rome was exerted in its behalf, and under his influence rich and noble ladies were led to retire from the world and consecrate themselves, amid the solitudes of Palestine, to a life of devotion.¹ The labours of Martin of Tours, and of Cassian at Marseilles, were especially successful in transferring Monachism westwards, until, in the course of the fifth century, thousands of devotees spread themselves through the south and middle of France into Britain and Ireland, carrying with them, it cannot be doubted, many influences of civilization, and forming in their settlement rallying points of Christian enlightenment and education, under the repeated incursions and devastations of barbarian tribes.

It may be readily conceived that such a fanatical spirit, in its growth and extension, had a constant tendency to degenerate from its primitive strictness, and to end in mere indolence and license. A yet more thorough system of organization was accordingly necessary to strengthen its widely-branching relations, and to consolidate it in its diffusion. And such a system was not long wanting. There arose among the monks of Italy one who saw the dangers to which Monachism was exposed, and who resolved to encounter them by a more systematic and efficient control. Benedict of Nursia was prepared for this great task by a self-discipline of the strictest character. Secluding himself

¹ The case of Paula and her daughter Eustochium, alluded to by Gibbon, vol. vi., p. 236, is well known.

Monach-
ism.

from all companionship, he spent three years of solitary devotion, unrelieved by a single visit, and his retreat unknown to any save a brother monk, who provided him with what he could spare of his own daily allowance of food, by dropping it by a rope to the foot of a steep rock near the grotto in which Benedict lived. Some shepherds at length discovered his retreat, and spread abroad the fame of the holy hermit. His influence was thus at once secured; he was invited to the rule of a neighbouring convent, and accepted it, although under protestation that the severity of the government which he would feel bound to establish would prove intolerable to those who gave him the invitation. It turned out as he supposed: the refractory monks even sought his life; and, leaving them in disgust, he retired once more to his solitude. This event only contributed the more to his fame; wealthy citizens of Rome reverentially sought him out, and entrusted their sons to him for education. He was gradually enabled to found and regulate, according to his own plan, twelve cloisters in the neighbourhood of his original seclusion; and subsequently, on retiring from the scene of his labours to a mountain at some distance, he laid the foundation of a monastic institution, which, under the name of the Abbey of Monte Casino, was destined to play an illustrious part in the annals of the Papacy.

Rigorous as were the personal austerities of St Benedict, he was convinced by experience that an undue severity of fasting and mortification was incompatible with a western climate and western habits. His rule, accordingly, in the ultimate form in which it obtained ascendancy throughout all the monasteries of the West, was characterized rather by its simplicity and order than by any particular severity. He aimed at subordination and discipline by a regular system of alternate labour and devotion, so that no period of the day remained unoccupied. Two hours after midnight the monks were aroused to vigils, and the time between this and daybreak was consumed in learning the psalms by heart, or some other similar study. At daybreak matins were performed, somewhat in the same manner as vigils, by chanting psalms and reading lessons from Scripture. The duty of private and mental prayer was also enjoined under certain restrictions. These early services were followed throughout the day by manual labour and reading. During summer the day was so divided that seven hours were given to the former occupation and at least two to the latter; during winter more time was given to study, but no alteration appears to have been made in the hours of labour. The Sabbath was entirely given to reading and prayer. A system of rigid temperance was of course enjoined, but of such a reasonable character that even the moderate use of wine was not forbidden.

The rule thus established by Benedict extended itself, as we have said, throughout the West, and for many years was instrumental in preserving the integrity and simplicity of devotion in its cloisters. With the gradual increase of riches, however, the Benedictine monasteries lost their primitive character, and became the seats of indolence and vice rather than of cheerful industry and piety.

Many attempts were made to revive the first vigour of the rule, and still more successfully to apply it in new forms, each of which in their turn achieved a great reputation, and powerfully helped the cause of the Papacy in the different countries into which they spread. In this manner arose the Order of *St Cluni*, and the *Cistercian* and *Carthusian* Orders—all branches, as it has been said, from the stem of St Benedict. (Waddington's *Church History*, vol. ii., p. 377.) One and all of these orders, it is remarkable, sprung from the teeming soil of France, in the south and east; and they follow one another, in their full prosperity, at the interval of about a century, beginning with the commencement of the tenth. As a monk of Cluni

it was that Hildebrand nursed those ambitious schemes which he afterwards carried out as Gregory VII. The immortal name of St Bernard is associated with the Cistercian Order, of which the Abbey of Clairvaux was a dependent; and the simple purity of the Carthusians, maintained for many years in the midst of surrounding license, acquired for them a great reputation and a strong settlement in almost every land of Europe, from the south of Italy to the northern shores of Scotland.

In the meantime other forms of monastic order had sprung up, the most notable and distinguished of which, dating from an early period, was the Order of St Augustine, which was destined to play so prominent a part in the advance of the Reformation. This order, at least in its origin—which, although claiming the sanction of the great teacher of the West, cannot be carried back so far—was chiefly composed of those who were looking forward to, or ordained to, the clerical profession—who were ecclesiastics, in short; while in the convents generally, according to their original constitution, there were but a few eligible or devoted to the ecclesiastical life. In the course of time, however, and from the increase of wealth, the number of those exclusively given to spiritual or ecclesiastical offices multiplied in all the convents,—a change which was greatly fostered by the institution of what were called *Lay Brethren*, upon whom the routine of manual labour and the discharge of all servile duties devolved.

There are still two further developments of the monastic system that claim notice, although our space will scarcely enable us to do more than mention them. These are the rise and establishment of the *Military* and the *Mendicant* or *Preaching* orders.

The former sprang up out of the close union subsisting between the ecclesiastical and the military professions in the middle ages, and especially out of the crusading spirit of the twelfth century, and the necessities of defence which it created. They are well known under the historical names of *The Knights of the Hospital*, *The Knights Templar*, and *The Teutonic Order*. They one and all took their rise in Palestine, and are associated with some of the most brilliant, and at the same time tragic, passages in the history of the church. They gradually disappeared about the time of the Reformation—the Knights Templar, especially, having been, two centuries previously, subjected to a fierce persecution, instigated and chiefly carried out by Philip IV. of France, who cherished towards them the most deadly and unrelenting hatred.

While the Military orders arose out of the external necessities of the church, and the warlike spirit kindled by the advance of Mohammedanism; the Mendicant orders originated in the internal dangers of the church from the encroaching spirit of reform and of free opinion. St Dominic (1191) acquired his fame as a preacher against the heresy of the Albigenses; and, recognising the effects following such eloquence in his own case, he framed the bold idea of establishing an order of Mendicant preachers, whose vow should especially bind them to the interests of the Holy See, and the extirpation of heresy. Innocent III. at first looked coldly on the project, but its obvious policy soon commended it to papal recognition; and St Dominic found himself at the head of one of the most devoted and illustrious societies which ever sought its own aggrandizement in the gratification of papal ambition and of orthodox vengeance. For it was under the shadow of the Dominican Order—although not, as it has been sometimes maintained, under the sanction of St Dominic himself—that the Inquisition inaugurated its bloody career. St Francis of Assisi was a contemporary of St Dominic, and pursued, independently of him, a similar course of fanatical activity. Enthusiastic almost to insanity, with a temperament capable of sustaining the most intense and prolonged raptures of

Monach-
ism.

Monaco
||
Monaghan.

devotion, and covetous of the most abject and degrading austerities, he burned to realize, in a definite social form, the pictures of evangelical purity and of self-renunciation which his imagination had conjured up. The story of his interview with Innocent III., when he first appeared before him with his plan, is well known. Hurried away from the holy presence as a mean madman—a convenient dream aroused the Pontiff to his mistake, and led him to lend all his countenance to a scheme which at first he repelled. While preaching was the characteristic feature of the Dominican rule, poverty was intended to be the chief distinction of that of St Francis; but the two orders gradually merged their distinctive peculiarities, and the members of each gave themselves equally to mendicancy and preaching. The history of these orders, as well as that of Jesuitism,—which may be said to be a development of the monastic spirit, but in such a distinct shape as to require separate notice,—is inseparably bound up with that of the Papacy. Their labours and rivalries form one of the most stirring chapters of human interest, of ecclesiastical ambition, and, we should add, so far at least as the Dominicans are concerned, of philosophical and theological activity.

Since the Reformation Monachism cannot be said to have manifested any inherent vitality or power. With the advance of modern civilization, its highest meaning and only conservative use are gone; and, so far as it still maintains itself in Europe, it must be held to be an opponent at once of genuine religious life and the advance of an elevated rational cultivation.

(For the more particular history of Monachism, the general reader may be referred to the Church Histories of Neander, Waddington, and Milman; and for a special account of its earlier phases, to Burgham's *Antiquities*, and the learned reader to Helyot's *Histoire des Ordres Monastiques*, Paris, 1714 and 1792.) (J. T.—H.)

MONACO, a small principality of North Italy, bounded on the S. by the Mediterranean, and on all other sides by the Sardinian States, under whose protection it is. It has a length of about 10 miles from N. to S., a breadth of 6, and an area of 52 square miles. The soil is fertile, and its climate mild, as it is sheltered towards the north by the lofty range of the Alps. Oranges, lemons, citrons, and other fruits are produced in abundance, and large herds of cattle are fed on the excellent pastures. Since the tenth century Monaco has been in the hands of the Grimaldi family, to whom it still nominally belongs; but it is now governed by the King of Sardinia, and garrisoned by his soldiers. The town of Monaco is situated on a lofty promontory 9 miles E.N.E. of Nice. It was called in ancient times *Ara Herculis Monocci*, from which its modern name is derived. The town is walled and fortified, but is completely commanded by the higher elevations towards the north. It has a good harbour, which is secure and well sheltered. Pop. about 1500. Mentone is a larger town than the capital, and contains about 4000 inhabitants. The entire population of the principality is about 7000.

MONAGHAN, an inland county of Ireland, in the province of Ulster, bounded N. by Tyrone, E. by Armagh and Louth, S. by Louth and Cavan, and W. by Cavan and Fermanagh. It comprises an area of 500 square miles, or 319,757 acres, of which 285,885 are arable, 21,585 uncultivated, 5816 in plantations, 304 in towns, and 6167 are under water; of the 21,000 acres of uncultivated land 14,500 are situated at elevations exceeding 800 feet, the remainder consisting chiefly of small detached bogs and marshy lands on the margins of lakes. About 7000 acres are capable of improvement by cultivation, 8000 acres might be improved by draining, and 6000 acres may be considered as incapable of improvement.

The general appearance of the surface is hilly, yet not rising into heights of considerable elevation. The principal

mountain range is that of Slievebeagh, a rugged and barren tract, extending south-westward along the Tyrone boundary into Fermanagh, and nowhere exceeding 1050 feet in altitude. North of Castleblayney, on the confines of Armagh, the Mullyash Mountain rises to the height of 1030 feet. There are no rivers of any consequence. The Finn, which rises near the centre of the county, scarcely merits the title of river until after its entrance into Fermanagh; and the Blackwater, forming part of the north-eastern boundary towards Tyrone, is the receptacle of many of the smaller rivulets which take their rise in Monaghan. Although deficient, however, in rivers of magnitude, it is amply furnished with streams of running water, well suited to the purposes of agriculture and of manufacturing industry. The number of lakes in this county is 184, thirty of which are considerable sheets of water, but the great majority are of very small extent. The most remarkable are Lough Egish, on Crieve Mountain, which supplies water for a long succession of mills and bleaching-grounds; Lakes Damby, Camm, and Oona. Others are celebrated for the beauty which they impart to the scenery; more particularly the chain of lakes between Coolehill and Ballybay, which ornament the demesnes of Dawson Grove and Bellamont Forest, and the beautiful Lough Muckno, which contains several islets, and forms part of the demesne of Castleblayney.

The soil is of various kinds. In the central and more level part of the county it consists of a rich limestone. The southern districts are partly of the same quality, and partly a deep clay, capable of a high degree of cultivation under judicious management. The north consists mostly of a stiff retentive clay, marshy in winter, and hardening quickly by the heat of summer, yet interspersed in many parts with tracts of valuable calcareous soil. Whilst the limestone formation predominates in the level districts, the more elevated portions exhibit traces of sandstone and basalt. Coal has been found between Moynalty and Carrickmacross, in more than one portion of a small basin which rests on a patch of the carboniferous limestone insulated within the slate district; but in beds so poor and scanty as not in any case to exceed 14 inches in thickness, which, in addition to the very difficult working caused by the strata dipping at a large angle, renders this coal district valueless in an economical point of view. Slates of good quality are quarried in Crieve Mountain. A lead mine was also worked there, but has long since been relinquished. Ochre, potters' clay, brick-clay, manganese, antimony, and fullers' earth are also found. There is a chalybeate spring at Drumtubberbuy, on Cairnmore, the water of which casts up a thick scum of ochre. A well near Clones is much celebrated for its efficacy in cases of jaundice, whence it has acquired its name of Granabuymore, or "the great yellow cure." This county has a large proportion of bog, which, together with its great number of lakes, and its exposure to the N.W. winds, renders the climate damp, though not unwholesome.

The state of agriculture has much improved during the present century. Descriptions given shortly after the year 1800 speak of the old country plough of clumsy construction, the slide-car without wheels, the conveyance of manure and field produce on horses' or asses' backs, and of spade-husbandry, as being generally prevalent. At present many of the improvements introduced by scientific agriculturists are to be seen in practice here, as far as they have been found consistent with the peculiar nature of the soil and climate. Ploughs on the most improved plan, Scotch carts, and implements of various kinds to supersede the improvident exertion of manual labour, are universal; yet in some parts, where the nature of the ground forbids the use of the plough, considerable tracts of land are still cultivated by the spade. The old, stunted, and ill-conditioned breeds of black cattle, sheep, and hogs, have given way to

Monaghan. the most esteemed British or foreign stocks, the character of which has not unfrequently been made more suitable to the agricultural localities by judicious crossings with the native breeds. The extent of land under each description of crop in 1850, 1855, and 1857 was,—

	1850. Acres.	1855. Acres.	1857. Acres.
Wheat	5,861	3,466	5,046
Oats	80,946	83,562	75,402
Barley, bere, rye, beans, and peas	7,467	3,711	4,095
Potatoes	22,105	25,399	28,915
Turnips	7,190	7,061	6,963
Other green crops	2,543	2,129	2,162
Flax	10,157	11,858	11,537
Meadow and clover	11,399	15,377	17,659
Total.....	147,668	152,563	151,779

Oats and potatoes are the principal crops, together with flax, for the growth of which the soil is peculiarly favourable. Clover is much encouraged, and few farmers are without a patch of it, however small. It is cut for green food, and found extremely economical. The tops of furze or gorse are also used, when pounded, as food for horses. The manure is formed of composts, of which lime and burned turf-mould are generally component parts; marl, though abundant, is little used; and the coal strata of the county afford a large deposit of gypsum, which, from its moderate solubility in water supplies lime for the growth of clover, &c., better than any other compound. The fences in some parts are of white thorn, interspersed with willows; in others a slight mound of earth serves rather to determine the boundary than to prevent trespassing. The county, which is now very bare of trees, was once almost a continuous forest, excepting the higher lands, which appear to be of a nature ungenial to the growth of trees. The numerous demesnes of the nobility and gentry, however, are richly embellished by plantations of modern growth. Ash and sycamore are much encouraged, the wood of the latter being in great repute for some parts of mill-machinery. Osieries are frequently to be found in the marshy bottoms at the foot of hills, and prove highly profitable.

The estates in land are of every value, from L.20,000 per annum to L.20, being partly held under grants of the escheated lands in Ulster in the time of James I., and partly arising out of the forfeitures in the time of Cromwell. The total number of farms or holdings exceeding one acre in extent, which in 1847 amounted to 23,255, has diminished to 19,000. Of this number about 3000 are between 1 and 5 acres in extent, 9000 between 5 and 15 acres, and 5000 between 15 and 30 acres; the remaining 2000 exceed 30 acres.

The mansions of the landed proprietors are numerous and elegant; the houses of the wealthier farmers, and more particularly of those who combine manufactures with agriculture, exhibit every indication of comfort; but the dwellings of the cotters and labourers are miserable in the extreme. Flesh-meat seldom forms a part of their diet; and those living in districts remote from towns are seldom able to procure any food but potatoes and butter-milk. Fuel is cheap and abundant in consequence of the quantity of bog.

The principal manufacture is that of linen, which has long been carried on with great spirit. The woollen manufacture is chiefly employed in supplying the domestic consumption. The sand or gritstone of Cairnmore has given rise to a manufacture of millstones there, which are in considerable demand. Coarse earthenware is manufactured at Glasslough; and a small ironwork at Smithborough, near Clones, supplies many of the agricultural implements used in the county.

The Ulster Canal, which intersects the county, passing the towns of Monaghan and Clones, affords water communication with Lough Erne and Lough Neagh; and the Dun-

kalk and Enniskillen and other railways will shortly furnish Monaghan the means of transit to the ports of Londonderry, Belfast, Drogheda, and Sligo.

The education of the county is chiefly in the hands of the national schools. In 1851 there was a total of 242 schools in Monaghan, with an aggregate of 9372 scholars. Of the schools in that year, 114 were national, 58 private, and 45 connected with religious bodies. The number of persons, five years old and upwards, who could neither read nor write, in 1841 and 1851, was ascertained by the census commissioners to be—

	Males.	Females.	Total.	Rate per cent.
1841.....	37,431	53,006	90,437	51
1851.....	22,270	31,859	54,129	42

The use of the Irish language in this county, as elsewhere, is on the decline.

Monaghan has few remains of antiquity. The most remarkable are two round towers,—one near the county of Fermanagh, in the burial-ground adjoining an ancient church at Clones; the other at Inniskeen, on the borders of Louth. The former, which is a very rude specimen of these singular monuments of antiquity, consisted of five storeys, the traces of which are still visible in the walls, its door being about 4 feet above the level of the ground. Near it is a large stone coffin, above ground, with a cover of the same material shaped like the roof of a house. The tower at Inniskeen, which is in a very inferior state of preservation, is unique, as having its door upon a level with the surrounding country, although this is supposed by some to be the effect of a modern alteration. Near Clones are two large raths, one in good preservation, exhibiting distinct traces of its fosses and ramparts; the other smaller and much decayed. Danish forts are numerous; but the county is singularly deficient in those ancient ecclesiastical and military remains which abound in the neighbouring counties of Meath, Louth, Armagh, and Fermanagh. The only monastic structure of which any vestiges remain is that of Clones, which was a foundation of regular canons. It was destroyed by Hugh de Lacy shortly after the arrival of the English; but was rebuilt soon afterwards, and protected by the erection of a castle in its neighbourhood. An abbey of Conventual Franciscans was founded at Monaghan by one of the M'Mahons, but was afterwards totally destroyed, and a castle erected on its site, which also was in a ruinous state in the reign of James I. The ruins of the castle of Mannan are to be seen at Donaghmoyné near Carrickmacross.

The population of the county has been ascertained at the following periods:—In 1821 it amounted to 174,697; in 1831 to 195,536; in 1841 to 200,442; and in 1851 to 141,813. In 1841 Monaghan was one of the most densely peopled counties in Ireland, having no less than 401 inhabitants to each square mile; in 1851, however, this number had diminished to 287,—a decrease in ten years of 114 persons for each square mile, being the greatest decline of population exhibited by any Irish county during that period.

This county was represented in the Irish Parliament by four members,—two for the county at large, and two for the borough of Monaghan. The latter were struck off at the Union, and no alteration has since been made.

The district now forming the county of Monaghan is supposed to have been occupied by a tribe of the Scoti in the time of Ptolemy. Subsequently it formed part of the territory of Uriel and Orgial, and was long known as "Mac-Mahon's Country," after a sept who for some time maintained their authority here. In the reign of Elizabeth it was reduced into shire-ground, and divided into the five baronies which still exist,—viz., Cremorne, Dartrey, Farney, Monaghan, and Trough. The whole of the county, which contains twenty-one parishes, is comprised within the diocese of Clogher.

Monaghan
||
Monarchy.

MONAGHAN, the capital of the above county, is situated near its centre, a short distance north of the Blackwater, a place of considerable thoroughfare and business in the linen trade and the sale of agricultural produce. Its ancient name was *Muinechan* (The Town of Monks), given to it from the religious establishment formerly existing there. The principal buildings are a market-house, erected by Lord Rossmore in 1792, a court-house, and a parish church. In the immediate vicinity of the town is a Roman Catholic chapel, a Presbyterian meeting-house in the New Market, the county infirmary, the diocesan school-house, the barrack for cavalry at the northern entrance of the town, an extensive county prison, and the union workhouse. Its population in 1851 amounted to 3484. The other towns in the county whose population exceeds 2000 are as follows:—Carrickmacross, 2534; Clones, 2333; and Castleblaney, 2084. (H. S.—R.)

MONARCHY. Literally translated, this imposing word signifies *single power*, implying government placed in the hands of one individual, that individual being the sole ruler of his people. Originally, the difficulty of obeying the wills of many different persons possessing authority, and not agreed as to the method of administration, led, in all probability, to the establishment of a monarchy. The corruption of the proto-republic thus gave birth to kings. A French philosopher has said, that when commonwealths become rotten they degenerate into monarchies; and a French emperor has given it as his opinion, that old monarchies can never be successfully converted into young republics. A third Frenchman has asserted that there exists no example of a people voluntarily destroying their own republic, and surrendering themselves and their laws to the irresponsible rule of a despotic monarch. The latter may, by force or cajolery, have imposed himself upon a nation; and, it may be added, that when the nation has been unfit for liberty, a salutary despotism may be for the country's good.

There is but one real basis for the stability of a monarchy,—love. The hatred of subjects denaturalizes the kingly system. According to Montesquieu, the true principle of monarchy is honour,—of a republic, virtue; which is very like many other of the distinctions drawn by Montesquieu, having in them very little difference indeed. It has been objected against what may be called the *legality* of monarchy, that if it had been of Divine origin, it would have rendered those subjected to it happy. Here again is a fallacy; for the monarchy of heaven itself was assailed by the angels who could not be happy under that Divine system.

The wellbeing of a people is perhaps never so perfectly secured as under a constitutional monarchy, which is, in fact, a republic with safeguards against revolution; or rather a commonwealth under which the people do not learn the "sacred right of insurrection," but accomplish all necessary revolutions quietly, surely, and according to law. When the accomplished Halifax was treating of despotic monarchs and turbulent republics in his *Character of a Trimmer*, he said:—"We take from the one the too great power of doing hurt, and yet leave enough to govern and protect us. We take from the other the confusion, the parity, the animosities, and the license, and yet reserve a due care of such a liberty as may consist with men's allegiance; but it being hard, if not impossible, to be exactly even, our government has much the stronger bias towards monarchy, which, by the general consent and practice of mankind, seems to have the advantage in dispute against a commonwealth." This advantage was acknowledged so long ago as the era of the Macedonian monarchy. The system was of course despotic; yet, if we may believe Quintus Curtius, the Macedonians had an innate affection for their kings:—"Ingenitam illi genti erga reges suos venerationem." But this is always advanced by interested rulers or writers in favour of despotism. The Poles fol-

lowed another system, which they considered the best,—Monarchy. namely, the elective system. It was a miserable failure; and yet the people, by which must be understood the nobles only, were wont to boast of it in these terms,—“In other kingdoms the monarch holds the people, but *we* hold the monarch.” The elective system is still followed in the case of that ecclesiastical monarch, the Pope, the electors of whom are supposed to be influenced by the Holy Ghost, in answer to the prayer, “Veni Creator Spiritus.” According to Bishop Jewel, the prayer was once replied to by the appearance of an owl in the conclave; and, according to Beranger, the reply to the invocation was, “Non,” dit le Saint Esprit, “je ne descends pas!” The state papers recently published having reference to the candidature of Wolsey for the papal throne, best show the system by which this elective monarchy was perpetuated. The third form is constitutional monarchy, according to which the sovereign is the first magistrate of a free people, with regard to whom there are laws in common, and rights and duties peculiar to each. And this constitutional monarchy may be in its origin elective, as that of England, when the nation, through Parliament, disinherited one family, elected a second, and then declared that the sceptre should be hereditary in such family, under certain stipulations. It may, however, be considered as a general rule, that *all* monarchies are the consequences of election on the part of the people. Except where a conqueror has chosen to rest on his right of the sword, there has seldom existed even an usurper who has snatched the crown without going through some ceremony by which he seemed to acknowledge, or the people were made to imagine, that the result was the effect of a cause traced to the love, veneration, free-will, and unshackled choice of the nation.

To a constitutional monarch laws are not manacles, but garlands. They adorn rather than oppress him. “There is a wantonness,” says the noble statesman whom we have already quoted, “in great power, which men are generally too apt to be corrupted with, and for that reason a wise prince, to prevent the temptation arising from common frailty, would choose to govern by rules, for his own sake as well as for his people’s, since it only secures him from errors, and does not lessen the real authority that a good magistrate would care to be possessed of. For, if the will of a prince is contrary either to reason itself or to the universal opinion of his subjects, the law, by a kind restraint, rescues him from a disease that would undo him. If his will, on the other side, is reasonable or well-directed, that will immediately becomes a law, and he is arbitrary by an easy and natural consequence, without taking pains or overturning the world for it.” For a monarch under such restraint there is no doubt a far greater degree of happiness than was ever enjoyed by despots, who feared their own guards next to dreading their own people, and *that*, too, when the acknowledged system of government was comprised in the talismanic words, “Quod principi placuit, lex esto!” It was in those days when monarchy was supposed to mean, and to be, simply the will, more or less idle, of the monarch, that men were slaves whose very breath could scarcely be drawn in freedom, even when the tyrant slept. The old lines by M. Bret illustrates this sentiment exactly; and, “done into English,” they run thus:—

“Upon his golden couch a tyrant dread,
In seeming tranquil sleep, reclined his head:
‘Is slumber made,’ said one, ‘for wretch so rare?
Does Justice nod, and Heaven its victim spare?’
‘Hush!’ said a fakir, ‘lest the noise you make,
E’en by a whisper, should the monster wake.
’Tis God who thus allows him to be blest,
That Innocence may have a moment’s rest.”

In classifying the great monarchies which have held the world in awe, St Augustine names but two,—the Baby-

Monarchy. Ionian and the Roman. The more usual method is to reckon the four great monarchies,—the Assyrian, the Persian, the Grecian, and the Roman. Legend, however, notices a monarchy older than the oldest of these,—namely, the Chaldean. This dynasty, which, like that of Bacchus, is wanting in records, is said to have commenced 460 years after the creation, and under ten kings to have lasted half a million of years! The name of the first king of this wonderful dynasty was Alorus,—in other words, “Shepherd of his People,”—a significant title to commence with, it must be allowed. We are accompanied by the wonderful even when we have the traditionary. Thus of Nimrod (or Belus, the Orion of the skies), the first king named by Moses, we are told in a pretty story, doubtless suggestive of the Divine origin of his kingship, that as he was one day abroad hunting, he saw in the heavens the figure of a starry crown. Taking the appearance to have special reference to himself, he engaged a craftsman to copy the sparkling pattern; and when this was fashioned into a sparkling diamond crown, Nimrod wore the same as a symbol of the authority and the favour conferred on him by Heaven.

The *Assyrian* empire properly commences with Ninus, the son of Belus, who reigned in Assyria, built Nineveh, and captured Babylon. This took place about 2060 years B.C. About 1200 years elapsed before Jonah told of the disastrous end, in the streets, of Nineveh; and Sardanapalus gave way to the conquering Arbaces 820 years before that of the Redemption. The empire continued to exist, however, with narrower limits, till 621 B.C., when the second Sardanapalus perished like the first, and Assyria was divided among the conquerors.

The *Persian* monarchy, which may be said to have annexed, or to have been included in, that of Assyria, dates from Zoroaster, 2115 B.C. Its early annals present only inextricable confusion; but we find Cyrus, King of Persia, master of all Asia in the sixth century B.C.; and the Persian empire stood, under alternations of glory and disaster, till the conquering Alexander subjected the country, and laid the foundation of the Greek empire, 331 B.C.

The *Greek* or *Macedonian* empire had, in Alexander, for its chief the twenty-first king of Macedonia. Such part of that wide empire as, after the death of Alexander, was comprised in Macedonia, fell before the Roman Æmilius Paulus, who pronounced Macedon a Roman province, and (167 B.C.) took its last king, Perseus, and his sons to Rome, where they walked in chains before the chariot of the conqueror.

The *Roman* monarchy, if it is to be dated from the building of the city by Romulus, commenced 752 B.C. Seven kings had reigned when, on the deposition of Tarquinius Superbus, the first consuls Brutus and Collatinus were appointed 509 B.C. The republic existed till the foundation of the imperial monarchy in the person of Julius Cæsar, 48 B.C. In the year of our Lord 363 the Roman empire was split into two divisions on the death of Jovian. The Western empire expired on the deposition of Romulus Augustulus, by Odoacer, King of the Heruli, A.D. 476. The Eastern empire, with Byzantium for its capital, existed nearly a thousand years later, its fall dating with the extinction of the imperial families of the Comneni and the Palæologi, A.D. 1453.

It would be impossible to name here all the other monarchies under which government has been administered; for of some, like that of Achaia, the names of the kings have been forgotten, and of others, like the Davids of Georgia, their acts are scarcely worth recording. In a tabular and alphabetical form, however, we give below some brief account of the existence of the principal monarchical systems which have won or exacted the obedience of mankind.

Alba.—Founded by Ascanius, 1152 B.C.; annexed to Rome by Tullus Hostilius, 665 B.C.

Algiers.—Founded as an independent monarchy in 1505 by Harush Barbarossa, a Sicilian renegade. Houssan, the thirty-second and last of the “Deys,” was dethroned and expelled by the French in 1830.

Arcadia.—Founded by Pelasgus, 1521 B.C. The last king, Aristocrates II., was stoned to death, and Arcadia made a republic, 681 B.C.

Argos.—Founded by Inachus, 1856 B.C. It existed as a monarchy upwards of seven centuries, but it subsequently became a republic.

Armenia.—The kings of Armenia were absolute over their own subjects, but the country itself was successively subject to the three great monarchies; and the Roman power became paramount in Armenia after the dethronement of Tiridates, A.D. 62.

Assyria.—(See above).

Athens.—Cecrops founded a monarchy here 1556 B.C. After a period of nearly 500 years, occupied by seventeen kings, royalty was abolished, on the singular ground that it would be impossible to find such another king as Codrus, the last of the line.

Austria.—(See below, *Germany*).

Babylon.—(See above, *Assyria*).

Bavaria.—This monarchy was established in 1805, when the elector, Maximilian Joseph, was declared king.

Belgium was formed into a kingdom in 1831.

Bithynia.—The first independent king was Dydalsus, 383 B.C. The last sovereign, Nicomedes, bequeathed the kingdom to the Roman republic, 75 B.C.

Bæotia.—This monarchy, founded by Cadmus, 1493 B.C., was abolished by the Thebans, 1215 B.C.

Bohemia was originally governed by dukes. The regal title was conferred by the Emperor of Germany on Vratislav in 1061. The crown was ultimately secured to the Austrian family by the treaty of 1648.

Bosphorus (Cimmerian).—A line of kings ruled here for about five centuries and a half. The last was Mithridates II., at whose deposition the Emperor Claudius made of the kingdom a province of the empire.

Brazil.—Erected into an empire, A.D. 1825.

Britain had its kings at the period of the Roman invasion. The first Christian king was Lucius, A.D. 179. Constantine added Britain to the Roman empire, A.D. 306. In the year 446 the Saxons were invited over by King Vortigern. The Saxon heptarchy was converted into a monarchy by Egbert, King of the West Saxons, A.D. 827. During the heptarchy, however, the most powerful king was called *Rex Gentis Anglorum*. From the establishment of the Norman line, A.D. 1066, the following are the dates and names of the successive dynasties that have possessed the English throne:—House of Lancaster, 1399; York, 1461; Tudor, 1485; Stuart, 1603; Brunswick, 1714.

Burmese Empire.—Founded by Alompra, from whom the reigning monarch is descended, in the middle of the last century.

Caliphate (The).—The first caliph was Abu Bekir (“Father of the Girl”), A.D. 632. After a succession of fifty-seven caliphs, the capture of Bagdad by Holagou Khan, A.D. 1258, put an end to the line in the person of Al Mostasim Billah. The Egyptian caliphate, which was the consequence of a schism, A.D. 908, flourished vigorously till the overthrow of the Eastern caliphate. When Selim I. annexed Egypt to Turkey in 1517, and received from the last of the Abbassides the key of the temple at Mecca, the Turkish sultan became the representative of the caliphs, and the “Father of the Faithful.”

China has been governed by twenty-two dynasties since the establishment of the first dynasty, 2207 B.C. The last monarch of the Chinese race, Whay-tsung, of the House of Ming, hung himself, 1628. Since his death the Mogul race of Tsing has reigned in China.

Monarchy. *Corinth.*—The monarchy was founded by Sisyphus 1376 B.C. The glory of Corinth dates from the establishment of the republic 582 B.C. It fell under the dominion of Rome 146 B.C.

Denmark.—In the Danish annals there is a list of fifty-six kings previous to the period when Margaret united the three crowns of Sweden, Denmark, and Norway. The present king is the twenty-first sovereign of Denmark since the last-named era.

Egypt.—Vulcan, or "Elementary Fire," is fabulously said to have been the first king of this ancient monarchy. There is nothing that is said of the ancient royal records that can be relied on till the period of the foundation of the dynasty of the Pharaohs in the person of Mizraim, 2188 B.C. This dynasty disappeared before the conquering Cambyses 525 B.C. The Persian dynasty held Egypt till its conquest by Alexander, at whose death commenced the line of Ptolemies, beginning 304 B.C. with Ptolemy Soter, and terminating 27 B.C. with Cleopatra, the thirteenth sovereign of that line. Since that period it has never been, in the strict sense of the word, an independent monarchy.

England.—See *Britain*.

Epirus.—The annals of this monarchy are obscure. Neoptolemus, son of Achilles, is said to have been the first king, 1170 B.C. It was annexed to Macedon, 220 B.C., about fifty years after the death of its last king, the great Pyrrhus.

Etruria.—The monarchical system observed in this ancient kingdom deserves a word of notice in this place. The country anciently comprised twelve different nations, each of which had its respective monarch, under the title of Lucumon.

France.—This monarchy popularly dates from Pharamond, the Frank invader of Gaul, A.D. 418; his second successor, Merovæus, or Merovig, gave name to the line Merovingian. The Carlovingians began with Pepin, the father of Charlemagne, A.D. 751; the House of Capet with Hugh Capet, A.D. 987; House of Valois, Philip VI., 1328; Bourbon, Henri IV., 1589; the empire, Napoleon I., 1804; Bourbons restored, 1814; House of Orleans, 1830 to 1848; second empire, 1852.

Germany.—The "Holy Roman Empire" in the west was restored by the Pope, A.D. 800, in the person of Charlemagne. His line has been thus followed:—By the Saxon line, A.D. 911; the Franconian line, 1024; the Suabian line, 1138 to 1212. The imperial throne was occupied by sovereigns of various houses, but chiefly of Austria, from the latter date till the year 1438, when Albert II., a descendant of Rudolph of Hapsburg, commenced the *uninterrupted* line of Austria. In 1804 the elective German empire was abolished; but its last emperor, Francis II., became Francis I., hereditary emperor of Austria.

Greece.—The modern kingdom of Greece was founded in 1832 in the person of the Bavarian Otho, the reigning monarch.

Hanover was erected into a kingdom in 1814, George III. of England being its first king. The succession being in the male line only, Ernest, Duke of Cumberland, succeeded to the throne on the death of William IV., King of England and Hanover, in 1837.

Hayti has been a hybrid sort of monarchy from the time Dessalines was crowned emperor in 1804.

Holland.—This commonwealth became a kingdom in 1806, under Louis Bonaparte. After the fall of the French empire, William Frederick, Prince of Orange, assumed the style of King of the Netherlands, 1815.

Hungary, having become free of the German empire in 997, Stephen, Duke of Hungary, was named by the Pope "Apostolic King" of that country. After a line of thirty-two monarchs, it became permanently annexed to Austria (1527) by the marriage of Anne of Hungary with Ferdinand of Austria.

Ilium.—This kingdom was founded by Dardanus 1480

B.C.; and at the overthrow of Priam, its sixth king, had lasted about three centuries.

India.—The Ghiznian dynasty, the first of which we have authentic records, was founded by the invader Mahmud Ghizni about the year 1000 of our era. After a succession of thirteen kings, Mahmoud Ghour established the short-lived dynasty of two kings, named after him, in 1186. The Patan or Delhi line, commenced in 1210 with the Kuttub-ul-Deen. The Mogul race of Timour commenced in 1525 in the person of the famous Zehir-ud-Deen Mahomed Baber, or the "Tiger." This once glorious race sank into insignificance in the middle of the last century, since which time the Mogul monarchs ceased to have any political importance until the temporary restoration of a Mogul chief, consequent on the outbreak of 1857.

Ireland.—The monarchical annals of Ireland contain lists of hundreds of kings, from the flood downwards. The first sole monarch, however, was Brian Boru, by election of the people, A.D. 1027. Nearly a century and a half later Henry II. of England became "Lord of Ireland."

Italy.—After the deposition of Romulus Augustus, A.D. 493, Odoacer, chief of the Heruli, assumed the title of "King of Italy;" the line existed about three quarters of a century, disappearing before the Lombard kings. In modern times the first and only crowned "King of Italy" was Napoleon I., A.D. 1805.

Japan has had an hereditary succession of ecclesiastical emperors from the year 660 B.C.

Jerusalem.—When the Crusaders captured the city, A.D. 1099, they established a kingdom which lasted eighty-eight years,—that is, till the recapture by Saladin, A.D. 1187. The first Christian king was the renowned Godfrey de Bouillon; its ninth and last was Guy de Lusignan. The monarchy was elective.

Jews.—The kingdoms of the Jews commence, it is almost superfluous to say, with Saul, chosen by lot; but it was not until the death of Solomon that the kingdoms divided into Judah and Israel, about 975 B.C. That of Israel lasted till Samaria was captured, and the ten tribes were carried into captivity by the Assyrians, 721 B.C. The kingdom of Judah existed till the year 587 B.C., when the temple and city were burned by the invading Nebuchadnezzar, who razed the walls of Jerusalem to the ground.

Lombardy.—The kingdom of the Lombards, a people from North Germany, existed from the year 570, when the Lombard soldiers at Milan proclaimed their chief Alboin king, till the year 772, when Charlemagne took possession of the country, and deposed the last king, Desiderius.

Lydia.—This kingdom boasted of a long line of monarchs, namely, from Argon, a descendant of Hercules, 1223 B.C., to Croesus, after whose deposition the "kingdom of the richest king among kings" was annexed to Persia by Cyrus, 548 B.C.

Macedon.—Named above.

Media, although at different times annexed to Assyria and Persia, claims mention as an independent monarchy from the period of its revolt against Arbaces, 820 B.C., till its conquest by Cyrus, 537 B.C.

Mexico, when discovered in 1518, had long been under the rule of a line of monarchs. After it threw off the yoke of Spain, Iturbide was made emperor in 1822, but was deposed, and was shot for attempting to restore the empire in 1824.

Morocco.—A line of kings in Fez was commenced as early as the end of the eleventh century; the line did not expire till the opening of the thirteenth. About two centuries later the foundations of the empire of Morocco were laid by Hascen, of the race of Sheerefs, at a time when there were still chiefs in Fez styling themselves kings. The empire, as comprising Morocco, Fez, Susiana, Tophilet, &c., was not, however, consolidated and established till the

Monarchy. seventeenth century, under Muley Abdel Melech, whose descendant is now on the throne.

Naples, or the *Two Sicilies*.—Goth, Lombard, Saracen, Norman, Gaul, and Spaniard, alternately occupied this locality. The treaty of Utrecht (1713) made Victor Amadeus, Duke of Savoy, King of the Two Sicilies, a title known as early as 1442. Subsequently the Savoyed king exchanged his crown for Sardinia, with a kingly title. The Two Sicilies belonged to the German empire till 1734, when Spain conquered them, and established there a line of Bourbon princes, of whom the present monarch is a descendant.

Netherlands.—See *Holland*, and *Belgium*.

Parthia.—The monarchy here lasted from the period of Arsaces, 250 B.C., to that of Artabanus V., A.D. 229, when it was annexed to the new kingdom of Persia.

Pergamus.—This kingdom was founded by Philetærus, 283 B.C. The last king, Attalus Philomater, bequeathed his kingdom to Rome, 133 B.C.

Persia was reconstructed by Ardisheer Babegan (Artaxerxes I.) Between the death of Alexander and this last period, Persia had seen the Syro-Macedonian dynasty of Seleucus and that of the Parthian Ash, or Arsaces. Artaxerxes I. was the founder of the Sassanian dynasty, which, amid triumphs and defeats, existed upwards of four centuries. Persia was subsequently possessed by the Caliphs and by the Tartars; afterwards by Timour Leng, at the beginning of the fifteenth century. A century later the disorganized monarchy was seized by Hussoon Uzun, chief of the tribe of "White Sheep," whose son Shah Ismael (1502) was the first of the nine shahs of the Suffavean dynasty. The Afghan line commenced with Mahmoud, A.D. 1722, and ended with the eighth and last monarch, Shah Rokh, 1750. After a few years of anarchy, the Zund dynasty succeeded in the person of Kureem Khan Zund. His last descendant, Lootf Ali Khan, was slain in 1794 by Aga Mahomed Khan, the founder of the Kujur dynasty, of which the reigning shah, Nasr-ul-Din, is the fourth sovereign.

Poland, at first governed by dukes, was raised to a sovereignty by papal authority under Boleslaus I., A.D. 999. The *Piast* kings of Poland were *native* sovereigns, and not a regular dynasty. The Jagellon line commenced at the close of the fourteenth century, and continued till the middle of the sixteenth. The monarchy existed in its elective form till 1795, when Stanislaus Poniatowski was deposed by Russia.

Pontus.—This kingdom was an offshoot from that of Persia. Darius Hystaspes, named "Artabazus," was the first sovereign of Pontus, 487 B.C. After the death of Mithridates VII., A.D. 40, the kingdom became a province of the Romans. Subsequently a new and Christian monarchy was established within a portion of the limits of the old kingdom of Pharnaces, Tigranes, and Mithridates. When the Crusaders, or "Latins," established their temporary empire at Constantinople, a dynasty of five successive sovereigns carried on the old succession from 1204 to 1261, under the name of the Greek empire of Nicæa. In the last-named year Michael Palæologus recovered Constantinople from Baldwin II.

Popes of Rome, as elected monarchs with temporal power, claim a word of notice in this record. Stephen II., the ninety-ninth pope, who was elected in 752, was the first who united the sovereign temporal and ecclesiastical dignities, in which he has been followed by 169 orthodox successors, one only of whom was an Englishman (Nicholas Breakspeare of St Albans), Adrian IV., 1154–1159.

Portugal.—The monarchy here dates from A.D. 1139, when Alphonso, Count of Portugal, was proclaimed king by the army, after defeating the Moors at Ourique. With the exception of the period 1580–1640, when Portugal was a province of Spain, and that of the French occupation in

the present century, the independent monarchical system **Monarchy.** has been uninterrupted in Portugal.

Prussia, after being governed since 1134 by margraves, electors, or dukes, was raised to a kingdom in 1701. It has had six kings, of whom the present, Frederick William IV., began to reign in 1840.

Rome.—See above.

Russia.—From the period of Ruric, 862, to the commencement of the sixteenth century, the Russians were governed by sovereign dukes, called of Kiev, Vladimir, or Moscow. In 1533 Ivan Vasilievitch assumed the title of "Czar," and that title Peter the Great exchanged in 1708 for that of Emperor.

Sardinia or *Piedmont*.—See also *Naples*. The first king of Sardinia was Victor Amadeus, 1713. The present monarch, Victor Emanuel II., is the eighth of the line, four sovereigns of which have abdicated.

Scotland.—The Scottish annals name kings of Scotland as far back as the period of Alexander the Great; but it will suffice to state here, that Kenneth MacAlpine, by uniting Scots and Picts, became the first sole monarch of Scotland, A.D. 843. From that period till the accession of James VI. to the throne of England, A.D. 1567, the government was administered, more or less independently, by above forty kings.

Spain.—Few nations have seen so many different monarchical systems as Spain. At length the various crowns of the kingdoms of Oviedo, Navarre, Cordova, Castille, Leon, Barcelona, Aragon, and (Moorish) Granada, were united on the head of Ferdinand V. in 1512, since which period fourteen sovereigns have successively occupied the throne.

Sparta (Lacedæmon).—This celebrated republic under kings, some of whom were puppets and many were "absolute," enjoyed a long but a chequered career. The rule of kings begins with Lelex, 1516 B.C., and nearly thirteen hundred years elapsed before royalty was totally abolished.

Sweden.—Between the year 1001, when Olaf Schoet Konung was elected first king of Sweden, to the year 1393, when the tyranny of Albert of Mecklenburg was followed by revolt, and that by anarchy, Sweden reckons twenty-one monarchs. In 1397 the three northern kingdoms were governed by one sovereign, but this union was repealed in 1523, when the patriotic Gustavus Vasa ascended the throne. The reigning monarch, Oscar, is the son of Charles John Bernadotte, originally a private soldier in the army of Louis XVI. of France.

Syria.—See *Assyria* and *Persia*.

Thrace.—The government here was originally monarchical, but divided among independent princes. It was annexed to the Macedonian empire about 335 B.C.

Turkey.—This monarchy established itself in Europe by the capture of Constantinople under Mahomed II. in 1453. That sultan was the ninth of a line founded in Asia by Othman, A.D. 1299. Abdul Medjid is the twenty-fifth sultan since the fall of the great Christian capital in the east of Europe.

Vandals and Goths.—The Italian monarchy of the latter has been already noticed. About the end of the fourth century they founded a kingdom in Spain, which expired in the eighth century with Roderick, their last king. In the year 428 Genseric crossed from Spain, and established the dynasty of Vandal kings in Africa. The line consisted of six monarchs, with the last of whom fell modern Carthage, Arianism, and the royal Vandal line, before the conquering sword of orthodox Belisarius, A.D. 534.

Wurtemberg, formerly a ducal electorate, became a kingdom at the close of 1805, of which the reigning king, William I., is the second sovereign, having succeeded his father Frederick in 1816.

By the above list the reader may learn in what period the strongest empires have fallen into decay, and may safely

Monasteer ||
Moncey.

predict that the mightiest which have followed them will, like them, pass away, and all earthly distinctions shrink to nothing. When *all* crowns lie shivered, as one day they must, then will be applicable to the entire roll of once living monarchs the noble lines which Beaumont penned on the royal tombs in Westminster:—

“Mortality, behold and fear!
What a charge of flesh is here!
Think how many royal bones
Sleep within these heaps of stones!
Here *they* lie, had realms and lands,
Who now want strength to move their hands;
Where, from their pulpits, seal'd with dust,
They preach, ‘In greatness is no trust.’
Here's an acre, sown indeed
With the richest, royalest seed
That the earth did e'er suck in
Since the first man died for sin.
Here the bones of birth have cried,
Though gods they were, as men they died.
Here are wands, ignoble things,
Dropt from the ruin'd state of kings.
Here's a world of pomp and state
Buried in dust, once dead by fate.”

(J. D-R-N.)

MONASTEER, a seaport-town of Tunis, on the Mediterranean, 85 miles S.E. of the town of Tunis; Lat. 35. 45. N., Long. 10. 49. E. It has a citadel, a harbour, manufactures of woollen stuffs, and a considerable trade. Pop. 12,000.

MONASTIR, or BITOLIA, a town of European Turkey, capital of a department of the same name, in the province of Macedonia, is situated on the Vestrizza, at the edge of a large plain, 90 miles W.N.W. of Salonika. Most of the commercial intercourse between Albania and the Ægean is carried on through it; and it is the centre of all military operations in Albania, Macedonia, Thessaly, and Bosnia. Pop. 15,000.

MONCEY, BON-ADRIEN JEANNOT, Duc de Conégliano, was the son of an advocate, and was born in 1754 at Moncey, the village near Besançon of which he afterwards assumed the name. In 1774 his relations, yielding to his master-passion for a soldier's life, allowed him to enrol in the gendarmery of Luneville. After passing into the volunteers of Nassau-Siegen, and then into the “Chasseurs Cantabres,” he became captain in 1791; and in 1794 we find him, as general-in-chief, defeating the Spaniards at Villa Nova. Chancing to be in Paris at the revolution of the 18th *brumaire*, he zealously supported Napoleon, and thus opened a path to future preferment. He was appointed by the First Consul inspector-general of the gendarmery, and in 1804 was rewarded with a marshal's baton, the title of Duc de Conégliano, and the rank of grand officer of the Legion of Honour. In 1808 he commanded in the Spanish province of Catalonia, but was recalled by Bonaparte to the command of the gendarmery. In 1813 he received the additional appointment of commander-in-chief of the Parisian National Guard, and was entrusted with the protection of the city during the Russian campaign of Napoleon. No one was more active during the defence of the capital in 1814 than Marshal Moncey. He organized the National Guard of Paris, and was among the last to lay down his arms after the capitulation of the city. At the beginning of the Hundred Days his submission was tendered to the Bourbons, but was withdrawn as soon as Napoleon landed from Elba. He was nominated president of the commission for the trial of Marshal Ney in 1815; yet, rather than accept this nomination, he chose to be deprived of all his titles and to lie for three months in the prison of Ham. In 1816 he was restored to his dignities, and was received into the favour of the king. On the outbreak of the Spanish war in 1823 Moncey was far advanced in age; he accepted, however, the command of

a division, and served in Catalonia with all the fire and vigour of his prime. He died in April 1842.

MONCOLIERI, a town of Sardinia, North Italy, is pleasantly situated on the slope of a hill, near the right bank of the Po, 5 miles S. of Turin. The town is entered by two gates. It possesses an ancient palace, two handsome churches, several convents, an elegant college, several schools, a town-hall, a theatre, and an hospital. Manufactures of earthenware, tiles, cabinet-work, and silk, are carried on; and the town has a considerable trade in cattle, for which there is a fair in October. Pop. 9129.

MONCREIFF, SIR HENRY WELLWOOD, Baronet, D.D., an eminent Scottish divine, was the son of the Rev. Sir William Moncreiff and Catherine Wellwood, and was born on the 7th February 1750, at Blackford, a parish in Perthshire, of which his father was minister. After completing his elementary education at the parochial school of Blackford, he repaired to the university of Glasgow in 1763, with the view of pursuing his studies for the Scottish church. In the midst of a brilliant collegiate career he had the misfortune to lose his father. The patrons of the charge thus left vacant at once resolved to reserve the living for young Sir Harry, who had already given such promise of future eminence. He removed to Edinburgh in 1768 to prosecute his theological studies; and on the 15th August 1771 was ordained minister of his native parish. The superior talents of the young preacher early attracted the attention of the Scottish metropolis; and in October 1775 he was appointed minister of St Cuthbert's parish in the city of Edinburgh. Here he commenced the arduous duties of his office with great zeal, and continued to labour with remarkable energy, at once for the spiritual advancement of his parish and for the general good of the Scottish church. He was possessed of talents which might have won for him a bright reputation in any of the higher walks of public distinction, but he preferred the more exalted, if less ambitious career of fulfilling the pious duties of the Christian pastor, and of freeing his church from what he conceived to be serious barriers to her spiritual progress. “Had he not preferred his church to every other object,” says Lord Cockburn, “there is no public honour to which he might not have fought his way.” (*Life of Lord Jeffrey*, vol. i., p. 188). When Sir Harry entered upon public life the moderate party was dominant in the Scottish church, and political independence was seldom to be met with. Worldly interest and his own secular rank might have inclined him to the majority, but he at once took a decided position with the liberal and evangelical party. He soon became their leader and oracle; and among the people his “mere name,” says Cockburn, “was a tower of strength.” He was unanimously chosen moderator of the General Assembly of his church in 1785, and during his subsequent career had the same honour repeatedly conferred upon him. He possessed great power and energy as a debater, and was distinguished for soundness of judgment and unflinching integrity. The writer just quoted, who knew Sir Harry well, remarks in his *Memorials of his Time*, p. 234,—“In comparison with him every other churchman who has appeared since I knew the world must withdraw. Nothing that I could say would express one-half of my affectionate and reverential admiration of this great man.” He shone more on the platform than in the pulpit; and public speaking, rather than literary labour, seemed to be his peculiar sphere. As a writer he was comparatively feeble. His *Life of Dr John Erskine* is in no way remarkable; and his three volumes of sermons do not possess very high merits. They were published in 1829 and 1831, with a brief memoir by his son, Lord Moncreiff. His opinions were uniformly liberal and charitable, and he was characterized by very great benevolence. He took a deep interest in whatever was calculated to relieve suffering or encourage merit.

||
Money.

Among his personal friends he numbered the most distinguished names in Scotland during his time. He died in August 1827, leaving his title to his son James Wellwood Moncreiff, who had been chosen Dean of Faculty during the previous year. Sir James was born in 1776, and was educated at Edinburgh, Glasgow, and Oxford. He devoted himself entirely to the law, but inherited much of his father's zeal for the evangelical cause of the Presbyterian Church and for the politics of the Scottish Whigs. He was a man of an energetic mind, and was distinguished for great zeal and purity. So exceedingly conscientious was he, that Lord Jeffrey, who had the greatest regard for him, used to call him "the whole duty of man." He was raised to the bench under the title of Lord Moncreiff in 1829. He died on the 30th of March 1851.

MONDONĒDO, a town of Spain, Galicia, 30 miles N.N.E. of Lugo. The streets are paved and clean, and the houses generally commodious. The cathedral, commenced

in 1221, has an image of wonderful remedial power, said to have been conveyed from London at the Reformation. The town and neighbourhood was sacked by Mathieu in 1809. Pop. 6305.

MONDOVI, a town of Sardinia, capital of a cognominal department in the province of Coni, and see of a bishop, stands on a hill near the Ellero, 53 miles W. of Genoa. The town proper, or Piazza, is situated on the summit; and the three suburbs of Carazzone, Brea, and Piano, on the sides and at the foot of the hill. The upper town is walled, and contains a large *piazza* of a hexagonal shape, a cathedral, four other churches, an episcopal palace, several convents, and a royal college. The manufactures consist of woollen and cotton stuffs, silk, leather, iron, earthenware, &c.; and the trade is considerable. Mondovi was the scene of a victory gained by Napoleon in 1796 over the Sardinian troops under Colli; and three years later was taken and pillaged by General Moreau. Pop. (1851) 17,370.

Money.

MONEY.

MONEY¹ (Gr. *μονητα*, *νόμισμα*; Lat. *moneta*, *pecunia*, *nummus*; Fr., *monnaie*), the name given to the commodities or articles which the people of different countries universally accept, either voluntarily or by compulsion, as equivalents for their services, and for whatever else they may have to dispose of.

PART I.—METALLIC MONEY.

SECT. 1.—*Circumstances which led to the use of Money. Principal properties which all Commodities used as such ought to possess. Metallic Money not a Sign or a Measure of Value, but a real Equivalent.*

Circumstances which led to the use of money.

Were the division of labour unknown, and did individuals or families directly supply themselves with the articles required for their subsistence and accommodation, there would be no exchanges, and, consequently, no money. But, after this division has been established, the employment of money becomes necessary, or, at least, highly advantageous. A small part only of a man's wants is then directly supplied by his own exertions. The greater part is indirectly supplied by his exchanging services, or articles belonging to him, for such services or articles rendered by or belonging to others as he has occasion for, and they are willing to furnish. Every man thus lives by exchanging, or becomes in some measure a merchant, and the society itself grows to be what is properly a commercial society.

"But when the division of labour first began to take place, this power of exchanging must frequently have been very much clogged and embarrassed in its operations. One man, we shall suppose, has more of a certain commodity than he himself has occasion for, while another

has less. The former, consequently, would be glad to dispose of, and the latter to purchase, a part of this superfluity. But, if this latter should chance to have nothing that the former stands in need of, no exchange can be made between them. The butcher has more meat in his shop than he himself can consume, and the brewer and the baker would each be willing to purchase a part of it; but they have nothing to offer in exchange except the different productions of their respective trades, and the butcher is already provided with all the bread and beer which he has immediate occasion for. No exchange can, in this case, be made between them. He cannot be their merchant, nor they his customers; and they are all of them thus mutually less serviceable to one another. To avoid the inconveniency of such situations, every prudent man, in every period of society, after the first establishment of the division of labour, must naturally have endeavoured to manage his affairs in such a manner as to have at all times by him, besides the peculiar produce of his own industry, a certain quantity of some one commodity or other, such as he imagined few people would be likely to refuse in exchange for the produce of their industry."²

This commodity, or *Marchandise banale*, as it is termed by the French, whatever it may be, is *money*.

Different commodities have been used as money in different countries and states of society. Those nations which chiefly subsist by the chase, such as the ancient Russians, and the greater part of the Indians who occupy the unsettled portions of America, use the skins of wild animals as money.³ In pastoral societies cattle are sometimes used for that purpose. Homer tells us that the armour of Diomed cost only *nine* oxen, whilst that of

Commodities used as money.

¹ Etymologists differ respecting the derivation of the word money. Some contend that it comes from *monere* (*quia nota inscripta de valore admonet*), because the stamp impressed on coined money indicates its weight and fineness—(Bouteroue, "Recherches sur les Monnoyes de France, p. 1); and others that it originates in the circumstance of silver being first coined at Rome in the temple of *Juno Moneta*.—Suidas, in voce *Μονητα*.

² *Wealth of Nations*, M'Culloch's ed., in one vol., p. 10.

³ Storch, *Traité d'Economie Politique*, tom. iii. p. 16; Ulloa, *Mémoires Philosophiques sur l'Amérique*, tom. ii. p. 100. Skins, hides, or pieces of leather marked with a stamp (*corium forma publica percussum*) are said to have been used as money by the Carthaginians and Spartans, (Seneca, *De Beneficiis*, lib. v. c. 14. Eckhel, *Doctrina Numorum Veterum*, i. *Proleg.*, p. xx., etc.). This statement, which is not a little obscure, has been very differently interpreted; some critics contending that it merely refers to such entire skins or hides as were bartered for other things, while others contend that it is meant to designate small bits of leather, marked with a stamp, and (like our bank-notes) substituted for and representing real money. It seems, perhaps, most probable that both interpretations may be true, that is, that entire skins and bits of leather, marked with stamps, may have been used sometimes in the one way and sometimes in the other. The stamp on the skin or hide might represent its weight, and that on the bit of leather its nominal value, or the money to be given for it to the holder.

Money.

Glaucus cost a hundred.¹ The etymology of the Latin word (*pecunia*) signifying money, and of all its derivatives, would seem to prove that cattle (*pecus*) had been the primitive money of the Romans.² And that they had been used as such by the ancient Germans is obvious; for their laws uniformly fix the amount of the penalties to be paid for offences in cattle.³ In remoter ages corn was very generally used in agricultural countries, as money; and even now, nothing is more common than to stipulate for corn rents and wages. Other articles have been used in other countries. Salt is said to be the common money of Abyssinia.⁴ Cowries, a species of shells gathered on the shores of the Maldiv Islands, are used in smaller payments throughout Hindostan, and form the only money of extensive districts in Africa.⁵ Dried fish serves as money in Iceland and Newfoundland;⁶ and Adam Smith mentions that, at the period of the publication of the "Wealth of Nations" (1776), it was customary in a village in Scotland for workmen to carry nails, as money, to the baker's shop and the alehouse.⁷

Defects of these commodities.

But these articles universally want some of the principal properties which money ought to possess. Products must frequently be brought to market which are worth only part of an ox and part of a skin; but as an ox could not be divided, and as the division of a skin would most probably deprive it of part of its value, they could not be exchanged for such money. Divisibility is not, however, the only indispensable quality in a commodity used as a medium of exchange. It is farther necessary that it should admit of being kept for an indefinite period without deteriorating; that it should, by possessing great value in small bulk, be easily carried about; and that one piece of money of a certain weight and fineness, should be precisely equivalent to every other piece of money of the same weight and fineness. But none of the commodities specified above, as having been used as money, possesses these properties. Though cattle had been sufficiently divisible, they could neither be preserved, nor transported from place to place, without a great deal of trouble and expense; while, owing to the difference in their qualities, one ox of a superior might be worth two or three oxen of an inferior variety. It is plain, therefore, that they could not serve as money except in a very rude state of society, when the arts were almost unknown, and the rearing of cattle formed the principal employment. Corn is sufficiently divisible; but its bulk is far too great in proportion to its value to admit of its easy transportation, and it also is of very different and not easily appreciated qualities. Salt, shells, and fish, are all open to insuperable objections. Equal quantities of all of them differ very greatly in their values; some of them cannot be divided, and others cannot be preserved or transported without much loss.

These commodities were also deficient in a still more

important particular. Their value was not sufficiently invariable to permit of their being advantageously used as money. They were not durable or lasting, nor was it possible to adjust their supply so as to avoid sudden fluctuations of price. The occasional abundance and scarcity of pasture has a powerful influence over the price of cattle, which is still more seriously affected by the occurrence of epidemical diseases, and other contingencies. The fluctuations in the price of corn, arising from variations of the seasons, are too frequent and obvious to require to be pointed out. And in the islands where cowries are picked up, a strong gale from a particular point of the compass has frequently, in a few hours, sunk their value considerably. It was not, therefore, to be expected that such commodities should be either generally or permanently used as money in civilised societies. Parties would very frequently be unwilling to buy, or barter produce for articles which might, in a few weeks, or even days, lose a third or a half of their value.

Money.

The desire of uniting the different qualities of invariability of value, divisibility, durability, facility of transportation, and perfect sameness, doubtless formed the irresistible reasons which have induced all civilised communities to employ gold and silver as money. Though far from invariable, the value of these metals changes only by slow degrees; they are readily divisible into any number of parts, which may be reunited, by means of fusion, without loss; they do not deteriorate by being kept; their firm and compact texture makes them difficult to wear; their cost of production, especially of gold, is so considerable, that they possess great value in small bulk, and can, of course, be transported with comparative facility: and their identity is perfect, the pure gold and silver supplied by Russia and Australia having precisely the same qualities with that furnished by California and Peru. No wonder, therefore, when almost every property necessary to constitute money is possessed in so eminent a degree by the precious metals, that they have been used as such from a very remote æra. Their employment in this function is not ascribable to accident, to the genius of any individual, or to any peculiar combination of circumstances. It grew naturally out of the wants and necessities of society, on the one hand, and the means of supplying them possessed by these metals, on the other. They became universal money, as Turgot has observed, "not in consequence of any arbitrary agreement among men, or of the intervention of any law, but by the nature and force of things."

Gold and silver the fittest materials for money.

A considerable period must necessarily have elapsed, after the introduction of the precious metals into commerce, before they were used generally as money. But, by degrees, the various qualities which so peculiarly fit them for this purpose would become obvious; and, in

Introduction of gold and silver as money.

¹ *Iliad*, lib. 6, lin. 235. Garnier contends, in a note to his translation of the *Wealth of Nations* (v. p. 18, ed. 1822), that by oxen, in the statement now referred to, Homer did not mean the animals so called, but coins impressed with the figure of an ox. But though the oldest Attic and some other ancient coins are marked with an ox, it does not follow that cattle were not used as money previously to their being issued. Indeed, the fair presumption is, that that circumstance was the cause of their figures being impressed on the coins.

³ Storch, *in loco citato*.

⁴ *Wealth of Nations*, p. 10.

⁵ Dans les pays où le cuivre a trop de valeur pour pouvoir représenter celle des plus menues denrées, on est encore obligé lui substituer quelque autre matière plus commune. C'est cette circonstance qui a fait adopter aux Indiens l'usage des *cauris* en guise des petite monnaie. Cet usage pourroit paroître étrange dans les pays aussi riches et d'une civilisation aussi ancienne que le Bengale et l'Indoustan: mais le cuivre y est si rare, et les vivres y sont si bon marché, qu'une pièce de la valeur de 1 cop. et $\frac{1}{2}$ [about a halfpenny English] peut y acheter une quantité des denrées suffisante pour la subsistance journalière d'un homme du peuple. On est donc obligé de deviser la plus petite monnaie de cuivre en plusieurs fractions; et comme une monnaie d'aussi peu de valeur conteroit plus à fabriquer qu'elle ne pourroit valoir, on la remplace par un coquillage dont la nature fait presque tous les frais. Quelque mince que soit la valeur d'un *cauris*, elle suffit dans ces contrées fertiles pour acheter une pièce des bananes ou quelque autre fruit commun.—Le Goux de Flaix, *Essai sur l'Indoustan*, tom. i. pp. 143-226, quoted by Storch, *Economie Politique*, tom. iii. p. 133.

⁶ Smith, *ubi supra*; and Horrebow, *Description de l'Islande*, tom. ii. p. 90.

⁷ *Wealth of Nations*, loc. cit.

Money. consulting their own advantage, individuals would endeavour to exchange some portion of their produce for commodities which could be easily concealed or carried about, which did not deteriorate by being kept, and of which they could give a portion that would be equivalent to, and readily accepted for, any article they might afterwards wish to obtain. When first brought to market, gold and silver, like copper, iron, or any other metal, were in an unfashioned state, in bars or ingots. Sheep, oxen, corn, cloth, &c., were then bartered for gold or silver, exactly as they were bartered for iron, copper, tin, or anything else. The parties having agreed upon the *quality* and *quantity* of the metal to be given for the goods, the latter was ascertained by weight. Nor is this a mere conjectural statement, advanced in a later age to explain appearances, and resting on probability only. Aristotle¹ and Pliny² tell us, that such was, in fact, the method by which the precious metals were originally exchanged in Greece and Italy; and the sacred writings present us with a remarkable example of the prevalence of the same primitive practice in the East. We are there told that Abraham weighed four hundred shekels of silver, and gave them in payment of a piece of ground he had purchased from the sons of Heth.³ It is also mentioned that this silver was "current money with the merchant," an expression which evidently refers to its quality only; for, had it been coined, or marked with a stamp, indicating its weight and fineness, it would have been unnecessary to weigh it. These ancient practices still subsist in various countries. In many parts of China, gold and silver do not circulate as coin under the authority of a public stamp. When exchanged, they are cut into pieces, supposed to be nearly proportioned to the value of the article they are to be given for; and the pieces are then weighed to ascertain their precise value. This practice is also prevalent in other countries.⁴

Before the art of metallurgy was well understood, the baser metals were frequently used as money. Iron was the primitive money of the Lacedemonians, and copper of the Romans. But these metals deteriorate by being kept; and, besides this defect, the rapid improvement of the arts, and the consequent reduction of their price, speedily rendered their bulk in proportion to their value much too great to permit of their continuing to serve as money. Copper, however, is still advantageously used in the form of tokens, convertible into silver in very small payments. In Great Britain, copper pence and half-pence are rated far above their real value. But as their issue is exclusively in the hands of government, and as they are legal tender to the extent of one shilling only in any one payment, this over-valuation has not, for reasons which will be afterwards explained, had any bad effect.⁵

The trouble and inconvenience attending the weighing of the metal in every exchange of gold or silver for commodities, must have been early experienced. But the greatest obstacle to the use of unfashioned metals as money, would undoubtedly be found in the difficulty of determining their quality, or the degree of their purity,

with sufficient facility and accuracy. The operation of *assaying* is one of great nicety and delicacy; and, notwithstanding all the assistance derived from modern art, it is still no easy matter to ascertain the precise degree of purity of a piece of metal. In early ages, such an operation must have been performed in a clumsy and bungling manner. It is most probable, indeed, that when the precious metals were first used as money, their quality would be appreciated roughly by their weight and colour. A very short experience would, however, be sufficient to show the inexactness of conclusions derived from such loose and unsatisfactory criteria; and the devising of some method by which the fineness of the metal offered in exchanges might be easily and correctly made known, would very soon be felt as indispensable to the general use of gold and silver as money. Such a Coinage. method was not long in presenting itself. It was early discovered that the purity of the metal would be indicated, and the trouble and expense of weighing it avoided, by marking each piece with a *public stamp*, declaring its weight and fineness. Such seem to have been the various steps which led the ancients, at a very remote æra, to the introduction of coined money.⁶ It was an invention of the greatest utility, and has powerfully contributed to facilitate commerce, and to accelerate the progress of civilisation and the arts.⁷

"Without some article of known exchangeable value, Advan- such as coin, readily received as an equivalent for other tages of things, the interchange of commodities must have been coined money. very limited, and consequently the divisions of labour very imperfectly established. Now, money obviates these evils, and by a twofold operation, augments production. In the first place, it saves all that time and labour which, while the intercourse between man and man is carried on by barter, must frequently intervene before a person can be supplied with the quantity of the commodity which he wants. In the second place, and in consequence of its saving the time and labour which must otherwise be spent in effecting exchanges, it multiplies the transactions of mercantile industry, and thus allows the divisions of employment to be more thoroughly established. By the first operation, it disengages a very considerable portion of labour from an unproductive occupation, and enables it to receive a more useful direction. By the second operation, it increases in a very high degree the productive powers of the labour already usefully employed. It assists every man in availing himself of the skill and dexterity which he may have acquired in any particular calling, and promotes cultivation in a manner suitable to the climate and soil of different districts, and of different countries. And by both these operations, coined money increases to an extent, not easy to be calculated, the wealth of civilised communities."⁸

But however great the advantages attending the use of coins, their introduction did not, in any degree, affect the principle of exchanges. Equivalents are still given

⁷ The Roman jurists have given a brief, but clear and comprehensive, account of the circumstances which led to the use of coined money.—*Origo emendi vendendique a permutationibus cepit. Olim enim non ita erat nummus; neque aliud merx, aliud pretium vocabatur; sed unusquisque, secundum necessitatem temporum ac rerum, utilibus inutilibus permutabat, quando plerumque evenit ut quod alteri superest alteri desit. Sed quia non semper, nec facile concurreret, ut, cum tu haberes quod ego desiderarem, invicem haberem quod tu accipere velles, electa materia est, cuius publica ac perpetua æstimatio difficultatibus permutationum æqualitate quantitatis subveniret; eaque materia forma, publicè percussa, unum dominiumque, non tam ex substantiâ præbet quam ex quantitate; nec ultra merx utrumque, sed alterum pretium vocatur.*—(Dissert., lib. xviii., tit. i., *De Contr. Empt. Leg. i.*)

Torrens *On the Production of Wealth*, p. 305.

Money.

Coins not
signs of
value: in
what sense
measures
of value.

for equivalents. The exchange of a quarter of corn for an ounce of pure unfashioned gold bullion, is undeniably as much a barter as if the corn were exchanged for an ox, or a barrel of beer. But supposing the metal to be formed into a coin, that is, impressed with a stamp indicating its weight and fineness, that circumstance would evidently make no change in the terms of the barter. The coinage saves the trouble of weighing and assaying the bullion, but it does nothing more. A coin is merely a piece of metal of a known weight and purity, and the commodities exchanged for it are always held to be of equal value. And yet these obvious considerations have been very generally overlooked. Coins, instead of being viewed in the same light as bullion or other commodities, have been regarded as something quite mysterious. They are said to be both *signs* and *measures* of value. But a sovereign is not a sign, it is the thing signified. A promissory-note payable on demand, or at some stated period, may not improperly be considered as the sign of the specie to be paid for it; but that specie is itself a commodity possessed of real exchangeable worth. It is equally incorrect to call money a measure of value, at least in the peculiar sense in which that phrase is commonly understood. Gold and silver do not measure the value of commodities, more than the latter measure the value of gold and silver. Everything possessed of value may either measure, or be measured by, everything else possessed of value. When one commodity is exchanged for another, each measures the value of the other. If the quatern loaf sold for a shilling, it would be quite as correct to say, that a quatern loaf measured the value of a shilling, as that a shilling measured the value of a quatern loaf.

Standards
of value.

The quality of serving as a measure of value is, therefore, inherent in every commodity. But the slow degrees by which the precious metals change their value, renders them peculiarly well fitted for forming a standard by which to compare the values of other and more variable articles. To this standard reference is almost always made in estimating the value of products in civilised countries. We do not say that one man is worth a thousand acres of land, and that another is worth a thousand sheep, but we ascertain for how much gold or silver the land and the sheep would respectively exchange, and then say that their proprietors are worth so much money. But in this there is nothing mysterious. We merely compare the value of one commodity with the value of another. And as coin or money is the most convenient standard of comparison, the value of other commodities is usually estimated or rated in it.

Non-existence of an
abstract or
ideal
standard.

It is obvious, from this statement, that the exchange of one commodity, or set of commodities, for another, may sometimes be adjusted by referring to money, without any money being actually in the possession of either of the parties to the exchange. If a horse, for example, commonly sold for £10, an ox for £5, and a sheep for £1, the animals might be exchanged in this proportion without the intervention of money. The frequent recurrence of transactions of this kind seems to have given rise to the notion of an abstract or ideal standard of value. Thus, instead of saying that a horse is worth £10, an ox £5, &c., it has been contended that it might as well be said that they are respectively worth 10*x*, 5*x*, and

Money.

1*x*; and, since the comparative values of commodities may be as clearly expressed in this way as in sums of money, that the latter may be discarded as a standard, and a set of arbitrary terms adopted in its stead. But those who argue thus completely mistake the nature and functions of a standard. Its object is not merely to mark the known relations between different commodities, but also to enable those which are unknown to be readily discovered. And although a series of arbitrary terms may serve well enough for the first of these purposes, it is quite impossible that it can ever serve for the second. This, however, is the principal object of a standard; and it is sufficiently plain that nothing can be used as such unless it possess the same properties as the things with which it is to be compared. To measure length, a standard must have length; to measure value, it must have value. The value of commodities is ascertained by separately comparing them with money, and we express their relation to each other by stating the result of our inquiries; that is, by mentioning the number of dollars, of pounds, or of fractions of a pound, they are respectively worth. And, when any new commodity is offered for sale, or when any change is made in the cost of an old one, we ascertain its relation to the rest, by comparing it with a dollar or a pound. It would be impossible, however, to do this, were the terms dollar or pound purely arbitrary, and referable to no really valuable article. We might as well try to estimate distances by an imaginary inch or an imaginary foot, as to estimate prices or values by an imaginary shilling or an imaginary sovereign. When we say that an ox is worth £5 and a sheep £1, we not only mean that each is worth a certain amount of gold or silver, but also, that when an ox and a sheep are compared together—that is, when the one serves as a standard by which to estimate the value of the other—one ox is worth five sheep. But suppose that we wish to ascertain what is the relative value of some other commodity—a hat, for example—to oxen or sheep. Of what use would it be to be told that one ox was worth five sheep, or that when the value of an ox was represented by the term “5*x*,” the value of a sheep was represented by the term “1*x*”? It is not the relation between oxen and sheep, but the relation between these animals and hats, that we are desirous of learning. And, though this relation may be learned by comparing the cost of oxen and sheep with the cost of hats, or by ascertaining for how much of some other really valuable commodity an ox, a sheep, and a hat will respectively exchange, it is obvious it will never be learned by comparing them with *x* or *z*, or other arbitrary term or symbol. It would not, in truth, be more absurd to attempt to ascertain it by comparing them with the hieroglyphics on an Egyptian sarcophagus. Nothing that will not exchange for something else can ever be a standard or measure of value. Commodities are always compared with commodities, and not with abstract terms. Men go to market with real values, or their equivalents, in their pockets. And it is to something possessed of real worth—to the gold contained in a sovereign, and not to the word sovereign—that they always have referred, and must continue to refer, in estimating value.¹

This principle has been neatly and perspicuously stated by Locke:—“Men, in their bargains,” says he, “contract not for denominations or sounds, but for the

¹ The following passage of Montesquieu has often been referred to in proof of the existence of an ideal standard:—“Les noirs de la côte d’Afrique ont un signe des valeurs sans monnaie; c’est un signe purement idéal fondé sur le degré d’estime qu’ils mettent dans leur esprit à chaque marchandise, à proportion du besoin qu’ils en ont; une certaine denrée, ou marchandise, vaut trois macutes; une autre, six macutes; une autre, dix macutes; c’est comme s’ils disoient simplement trois, six, dix. Le prix se forme par la comparaison qu’ils font de toutes les marchandises entre elles: pour lors, il n’y a point de monnaie particulière, mais chaque portion de marchandise est monnaie de l’autre.”—*Esprit des Loix*, liv. xxii. cap. 8.

But, instead of giving any support to the notion of an abstract standard, this passage might be confidently referred to in proof of its

Money. intrinsic value; which is the quantity of silver (or gold) by public authority, warranted to be in pieces of such denominations. And it is by having a greater quantity of silver (or gold) that men thrive and grow richer, and not by having a greater number of denominations; which, when they come to have need of their money, will prove but empty sounds, if they do not carry with them the real quantity of silver (or gold) that is required."

In common mercantile language, the giving of money for a commodity is termed *buying*, and the giving of a commodity for money, *selling*. *Price*, unless when the contrary is particularly mentioned, always means the value of a commodity rated in money.

Having thus endeavoured to explain the circumstances which led to the introduction of money, and to show what it really is, and what it is not, we proceed to investigate the laws by which its value is regulated. It is chiefly from the prevalence of erroneous opinions on this subject, that the theory of money has been so much misunderstood.

SECT. II.—*Circumstances which Regulate the Exchangeable Value of Money.*

Value of money :

This branch of our subject naturally divides itself into two parts: 1st, An inquiry into the principles which regulate the exchangeable value of money when the power to supply it is free or unfettered; and, 2d, An inquiry how far these principles are affected by the operation of monopoly.

When the power to supply it is unrestricted.

I. There does not seem to be much room for difference of opinion respecting the circumstances which regulate the value of the precious metals, and their distribution throughout the various countries of the globe. Bullion is a commodity, on the production of which competition operates without restraint. It is not subjected to any species of monopoly, and its value in exchange must, therefore, depend on the cost of its production, that is, on the quantity of labour required to produce it and bring it to market.

If the same quantity of labour always produced the same quantity of bullion, its value would be invariable, and it would constitute a standard by which the variations in the exchangeable value of other commodities

Money. might be correctly ascertained. But this is not the case with bullion or anything else. Its value fluctuates like that of other articles, not only according to the greater or less productiveness of the mines from which it is extracted, but also according to the varying skill of the miners, the improvement of machinery, and other circumstances.

In his treatise on *Political Economy*, Say has a chapter entitled "*De la valeur que la qualité d'être monnaie ajoute à une marchandise.*" But a little reflection will convince us that this is a mistake, and that the circumstance of the precious metals being used as money adds nothing to their value. Say reasons on the hypothesis, which is equally at variance with principle and fact, that an increase of demand is always productive of an increase of value. The latter, however, depends upon the cost of production; and it is obvious that the cost of a thing may be diminished while the demand for it is increased, and conversely. This is so plain a proposition, as hardly to require to be substantiated by argument. And the instance of cotton goods, the price of which, notwithstanding the vast increase of demand, has been constantly on the decline during nearly a century past, is enough to convince the most sceptical of the extreme erroneousness of Say's conclusion. But, with regard to the precious metals, it is clear that under ordinary circumstances, or when mining is prosecuted under nearly the same conditions as other businesses, the capital employed in their production must yield the common and ordinary rate of profit; for, if it yielded more than that rate, there would be an influx of capital to the mining business; and, if it yielded less, it would be withdrawn, and vested in some more lucrative employment. And hence, though the demand for gold and silver should, from the adoption of some other commodity as an instrument of exchange, gradually become less, the value of the precious metals would not on that account be reduced. A smaller supply would, indeed, be annually brought to market, and a portion of the capital formerly engaged in the mining, refining, and preparing of metals, would be disengaged. But as the whole stock thus employed yielded only the average rate of profit, the portion which is not withdrawn must continue to do so; or, which is the same thing, gold and silver must continue to sell for the same price. It is true that where mines are, as they almost always

non-existence. Had Montesquieu said that the blacks determined the values or prices of commodities, by comparing them with the arbitrary term *macute*, the statement, though erroneous, would have been at least in point. But he says no such thing. On the contrary, he states distinctly that the relative values of commodities (marchandises) are ascertained by comparing them *with each other* (entre elles), and that it is merely the result of the comparison that is expressed in arbitrary terms.

So much for the weight to be attached to this statement, supposing it to be well founded. The truth is, however, that the term *macute* is not really arbitrary, and employed only to mark an ascertained proportion, but that it has a reference to, and is in fact, the name of an intrinsically valuable commodity. "On a bien dit," says l'Abbé Morellet, "que ce mot *macute* étoit une expression abstraite et générale de la valeur, et cela est vrai au sens où nous l'expliquerons plus bas; mais on n'a pas remarqué que cette abstraction a été conséquente et postérieure à l'emploi du mot *macute*, pour signifier une marchandise, une denrée réelle à laquelle on avoit longtems comparé toutes les autres.

"*Macute* en plusieurs lieux de la côte d'Afrique, est encore le nom d'une certaine étoffe: 'Chez les negres de la côte d'Angola,' dit le voyageur Angelo, '*les macutes* sont, des pièces de nattes d'une aune de long;' Jobson dit aussi que les *macutes* sont une espèce d'étoffe.

"Les étoffes ont toujours été l'objet d'un besoin très-pressant chez des peuples aussi barbares, dépourvus de toute espèce d'industrie.—Les nattes en particulier leur sont de la plus grande nécessité. Elles sont divisées en morceaux peu considérables et d'une petite valeur; elles sont très-uniformes dans leurs parties, et les premières qu'on a faites auroient pu être semblables les unes aux autres, et d'une bonté égale, sous la même dénomination; toutes ces qualités les ont rendu propres à devenir la mesure commune des valeurs."—*Prospectus d'un Nouveau Dictionnaire de Commerce*, p. 121.

The following extract from Park's *Travels* gives an example of a similar kind:—"In the early intercourse of the Mandingoes with the Europeans, the article that attracted most notice was iron. Its utility in forming the instruments of war and husbandry made it preferable to all others; and iron soon became the measure (standard) by which the value of all other commodities was ascertained. Thus a certain quantity of goods, of whatever denomination, appearing to be equal to a bar of iron, constituted, in the trader's phraseology, a bar of that particular merchandise. Twenty leaves of tobacco, for instance, were considered as a *bar* of tobacco; and a gallon of spirits (or rather half spirits and half water) as a *bar* of rum; a bar of one commodity being reckoned equal in value to a bar of another commodity. As, however, it must unavoidably happen that, according to the plenty or scarcity of goods at market, in proportion to the demand, the relative value would be subject to continual fluctuation; greater precision has been found necessary; and, at this time, the current value of a single bar of any kind is fixed by the whites at *two shillings sterling*. Thus, a slave, whose price is £15, is said to be worth 150 bars."—*Travels in the Interior of Africa*, 8vo. edit., vol. i. p. 39.

Further Considerations concerning Raising the Value of Money. Locke's Works, ii. 94. 4to. 1777.

Money.

are, of different degrees of productiveness, any great falling off in the demand for bullion might, by rendering it unnecessary to work inferior mines, enable the proprietors of the richer mines to continue their work, and to obtain the ordinary rate of profit on their capitals, by selling bullion at a reduced price. In this case the value of bullion would be really diminished; but this diminution would not be occasioned by a falling off in the demand, but by a greater facility of production. On the other hand, an increased demand for bullion, whether it arose from the suppression of paper money, or from a greater consumption of gold and silver in the arts, or from any other cause, would not be accompanied by any rise of price, unless, in order to procure the increased supply, it were necessary to have recourse to less productive mines. If the mines from which the additional supplies were drawn were poorer than those already wrought, more labour would be necessary to procure the same quantity of bullion, and, of course, its price would rise. But if no such increase of labour were needed, its price would remain stationary, though ten times the quantity formerly required should be demanded.

Production of the precious metals.

But though true under the circumstances supposed, these conclusions are often much modified in practice. Frequently, indeed, the production of the precious metals partakes very largely of the nature of a gambling speculation. When gold or silver is found in any particular locality, its abundance, and the chances which it affords to adventurers of enriching themselves, are uniformly exaggerated, and an excess of hands is attracted to the pursuit of the metal. In such cases, it commonly happens that, while a few individuals engaged in the business make fortunes, the great mass make little or nothing. But most people being sanguine enough to think that they will be found in the fortunate class, the supply of bullion may be largely increased, and its value reduced, even though the majority of those engaged in its production should be really carrying on a losing employment.

When the gold and silver mines of America first began to be wrought, the most extravagant ideas were entertained of their productiveness; so much so, that they were supposed to be able to bear a duty of half the produce. But it was soon found that the exaction of such a duty would occasion their total abandonment. It was consequently lowered, by successive reductions, to a tenth; and even this was felt to be oppressive, so that, in the end, the duty was fixed at a twentieth part, or five per cent. And, despite this reduction, the trade of mining was generally unprofitable. Ulloa says, that in Peru an individual who embarked in a mining speculation used to be considered as a ruined man, or as having adventured in a lottery, in which, though there were many great prizes, the blanks had a decided preponderance;¹ and, according to Humboldt, nearly the same thing was experienced in Mexico; the search after mines, and the working of them, being there looked upon as a sort of gambling adventure, in which many were ruined, while a few only attained to great wealth.²

It remains to be seen whether the result of the extraordinary discoveries in California and Australia will be different. We suspect, however, that it will not; and that in the lottery of these countries, as in that of Mexico and Peru, the blanks will greatly exceed the prizes. It is understood that last year (1856), there were in California above 100,000 persons engaged in the raising of gold, or in the employments subordinate to and immediately connected therewith. And if we estimate the

Money.

value of the labour of these parties at £100 a-year each, at an average, we shall not probably be beyond, but within the mark; and, on this hypothesis, it would require a sum of £10,000,000 to defray their mere wages. Now, it would appear from the accounts most worthy of credit, that the produce of the gold diggings, &c. of California in 1856, amounted to from £13,000,000 to £14,000,000; and, taking it at the latter amount, which is perhaps exaggerated, still it would only yield £4,000,000 of surplus, which, were it equally divided among the parties employed in raising it, would give £40 to each. But instead of being equally, it is most unequally divided; and, while a few have perhaps realised from £1000 to £2000, or upwards, it is plain that very many can have made little or nothing, not even ordinary wages. And this has also been the case in Australia. But the brilliant prizes, and the stories of cobblers and ditchers whom a fortunate chance has suddenly raised to opulence, have not failed to attract crowds of competitors. And the probability is, that the business of gold-raising will be zealously prosecuted, even though it should make a most inadequate return to the aggregate hands engaged in it. Under such circumstances, the supply of bullion may become, to a considerable extent, independent of the cost of its production; and the value of gold in the market may, for lengthened periods, depend chiefly on its quantity compared with the demand.

Although, therefore, it be true that, under ordinary circumstances, commodities are but seldom brought to market unless they sell at a price sufficient to repay the cost of their production, including therein a reasonable profit to the producers, yet many things occur to disturb the equilibrium between cost and price. And though, in the great majority of instances, such disturbances, when they do occur, are rarely of any very considerable permanency, such may not be the case with gold and silver. The circumstances connected with their production are so very peculiar, that they may be furnished for indefinite periods, and in large quantities, even when they do not really indemnify the great body of their producers.

After gold and silver have been brought to market, their conversion into coin, or manufactured articles, depends on a comparison of the profits which may be derived from each operation. Bullion would not be taken to the mint were it more profitable to send it to a silversmith; and the latter would not work up bullion into plate, if he could turn it to better account by converting it into coin. Hence the values of bullion and coin in countries where the mint is open to all, and the expenses of coinage are defrayed by the state, must very nearly correspond. When there is any unusual demand for bullion in the arts, coin is melted down; and when, on the contrary, there is any unusual demand for coin, plate is sent to the mint, and the equilibrium of value maintained by its fusion.

So long, therefore, as competition is allowed to operate without restraint on the production of gold and silver, their value will vary, as above stated. And, while gold or silver coins constitute the currency, the prices of commodities, or their values rated in such coins will vary, not only according to the variations in the values of the commodities themselves, but also according to the variations in the value of the metal of which the coins are made.

II. Happily it is not possible to monopolise or limit the

Money.
Value of
money
when the
power to
supply it is
restricted.

supply of the precious metals; but if such a thing were possible, or if none but government could use the mint, or issue coins, the value of the latter would no longer depend on their cost. Suppose, to illustrate the principle, that gold is used as money, that government issues a certain amount of coins and then shuts the mint; and that, after such limitation, the population of the country, and the products to be circulated, are largely increased. In such case it is plain that the exchanges which the limited amount of money would have to perform would be proportionally augmented. A smaller sum would, therefore, have to be appropriated to each transaction, or, which is the same thing, money prices would be diminished. This conclusion is so self-evident as to admit neither of doubt nor cavil. And, therefore, it appears that when the supply of money is limited, the amount of it given in exchange for commodities varies inversely as the demand, and is affected by nothing else.

That we might simplify the subject, we have assumed, in this statement, that the substitutes which may be used for money, and the methods by which it may be economised, were the same throughout the period, when the other changes referred to took place. It is easy, however, to allow for any variation in the one or the other. And, supposing this allowance to be made, it follows, if double the usual supply of commodities were brought to market in a country with a limited currency, that their money price would be reduced a half; and that, if only half the usual supply were brought to market, it would be doubled; and this, whether the cost of their production had increased or diminished. Products are not then exchanged for money, because it is a commodity which may be advantageously used in the arts, and has cost a certain quantity of labour, but because it is the universal equivalent, or legal tender, adopted by the society, and will, as such, be willingly received by every one. The remark of Anacharsis, the Scythian, that gold and silver coins seemed to be of no use but to assist in numeration and arithmetic,¹ would, if confined to a limited currency, be as just as it is ingenious. Sovereigns, livres, dollars, etc., would then really constitute mere tickets or counters for computing the value of property, and transferring it from one individual to another. And as small tickets or counters would serve for this purpose quite as well as large ones, and those of brass, tin, or paper, quite as well as those of gold, there can be no doubt that by sufficiently limiting its quantity, a currency, though destitute of intrinsic worth, may be made to circulate on a level with gold or silver, or higher, if it be desired.

When a currency is mixed, or consists partly of coin and partly of paper-notes immediately convertible into specified amounts of coin, the value of the notes is necessarily measured by, and is in fact identical with the value of the coins which may be obtained for them, and which they are truly said to represent. But when, as has often been the case, notes which are not convertible into coin are notwithstanding legal tender, then it is plain that their value cannot be in any wise dependent on the value of coins. Such notes are not representatives of money, but are themselves a variety of money. They circulate because their issuers have power to make them legal tender, and because money of one kind or other is indispensable. Notes of this description have little or no intrinsic worth, so that their marketable or exchangeable value depends entirely on the extent to which they are issued, compared with the business they have to perform. If their supply be sufficiently restricted, their value may be maintained on a level with that of gold, or even raised above it.

In their case everything depends on the discretion of the issuers. If they abuse their power, as they almost invariably do, by throwing too great quantities of notes on the market, their value is proportionally reduced; and if the issuers do not pull up in time, the notes will eventually become, like the assignats in France, wholly worthless.

Speaking generally, the value in exchange of a currency consisting of the precious metals is coincident with the cost of their production. If a sovereign commonly exchange for two or three bushels of wheat, or a hat, it is because the same labour is commonly required for its production as for that of either of these commodities; while, if with an inconvertible paper money, they exchange for a one-pound note, it is because such is the proportion which, as a part of the mass of commodities offered for sale, they bear to the supply of paper in the market. This proportion would, it is evident, be not only immediately, but permanently affected by an increase or diminution either of paper or commodities. But the relation which the latter bear to a freely supplied metallic currency is not permanently changed, except by a change in their cost, or in that of the metals.

We have already seen in how far these conclusions are liable to be affected by the peculiar circumstances under which gold and silver are frequently produced. But however much their value in exchange may diverge for a while from the cost of their production, its uniform tendency is to coincide with that cost; and though the value of bullion, as compared with other articles, may differ very widely at different periods, these differences are usually manifested by slow degrees. The vast extent of the surface over which the precious metals are spread, and the many purposes to which they may be applied, prevents even the largest additional supplies from suddenly reducing their value; while, on the other hand, their great durability prevents any sudden diminution of their quantity, and the influence of a falling off in the supply, from being speedily visible.

It may, therefore, be laid down generally, that the value of money depends on the quantity of it in circulation compared with the exchanges to be effected by its means, or with the business it has to perform. When, however, money consists of coins, their value is most commonly limited by, and proportioned to, the cost of their production; whereas, when it consists of paper, not convertible into coin, its value is exclusively determined by the magnitude of its issues, and has nothing to do with the cost of its production. That cost may, indeed, in its case, be regarded as zero.

Such seem to be the circumstances which regulate the value of money, both when the power to supply it is unfettered by any restraints, and when it is restrained and limited. In the former case, its value depends, like that of the greater number of commodities, on the cost of its production; while, in the latter case, its value is wholly unaffected by that circumstance, and depends on the extent to which it has been issued, compared with the demand.

The conclusions deducible from these principles are most important. A metallic currency, on the coinage of which a high seignorage or duty was charged, and a paper currency not convertible into the precious metals, have been occasionally seen to circulate at the same value with a metallic currency of full weight, and which had been coined at the expense of the state. No rational or consistent explanation of these apparently anomalous results could be given until the effects produced by limiting

Money.

General
conclusion
as to the
value of
money.

¹ Hume's *Essay on Money*.

Money. the supply of money had been appreciated. Now, however, that this has been done, these difficulties have disappeared. The theory of money has been perfected, and we may estimate, *a priori*, what, under any given circumstances, would be the effect of imposing a seignorage, or of issuing inconvertible paper.

SECT. III.—*A Moderate Seignorage on Coined Money advantageous. Principles which should regulate its amount.*¹

Reasons why a seignorage should be imposed on coins.

The governments of most countries have retained the power of coining exclusively in their own hands. In antiquity this privilege was reserved to prevent the confusion which would result from the circulation of coins of different denominations were individuals permitted to issue them at pleasure, and to give the public greater security that the stamp should truly indicate the weight and fineness of the metal.² And in more modern times it has been reserved for the same reasons, and also, as a means of increasing the national revenue. Much difference of opinion has, however, existed in regard to the policy of imposing a tax on coins. It has been contended that they ought in no circumstances to be charged with any duty; but that the expenses of the mint should always be defrayed by the public. In this opinion we cannot concur. The reasoning of Adam Smith, in favour of a moderate seignorage, appears to be quite unanswerable. A sovereign is more serviceable than a piece of pure unfashioned gold bullion of the same weight; for, while it is equally well fitted for being used in the arts, it is, which bullion is not, money or legal tender. In imposing a duty or seignorage on coins to defray the expense of coinage, government merely gets back the equivalent of the additional value conferred by the process on the bullion. And the truth is that those who carry gold to the mint would have no better reason for complaint were they charged with the expense of its coinage, than they would have, had they sent it to a jeweller's, that they were charged with expense of its manufacture into plate.

But there are other reasons why a seignorage ought to be exacted. Wherever the expense of coinage is defrayed by the state, gold or silver coins, and gold or silver bullion, are very nearly of the same value. And hence, whenever it becomes profitable to export the precious metals, coins, in the manufacture of which a considerable expense has been incurred, are sent abroad indifferently with bullion. It has sometimes been attempted, by prohibiting the exportation of coins, to prevent the loss that may thus be occasioned; but these efforts having proved singularly ineffectual, have been abandoned in this and most other countries. Admitting, however, that it were possible, which it certainly is not, to prevent or materially limit the clandestine exportation of coins, it is conceded on all hands to be quite nugatory to attempt to prevent their conversion into bullion. In this there is almost no risk. And the security with which their fusion may be effected, and the trifling expenses attending it, will always enable them to be melted down and sent abroad whenever there is any unusual foreign demand for the precious metals. This exportation would, however, be either prevented or materially diminished by the imposition of a seignorage or duty, equal to the expense of coinage. Coins being, by this means, rendered more valuable than bullion, it

would be sent abroad in preference to them, in the event of the exchange becoming unfavourable, or of gold becoming a suitable article of export. And if, as Adam Smith has observed, it became necessary on any emergency to export coins, they would, most likely, be re-imported. Abroad they are worth only so much bullion, while at home they are worth this much, plus the expense of coinage. There would, therefore, be an obvious inducement to bring them back; and the supply of currency would be maintained at its proper level, without its being necessary for the mint to issue fresh coins.

Besides relieving the country from the useless expense of coining money sent abroad as an article of commerce, a moderate seignorage would either prevent or materially lessen that fusion of the heavier coins, which always takes place whenever a currency becomes degraded or deficient in weight. Previously to the recoinage of 1774, the weight of bullion contained in the greater number of the gold coins in circulation was reduced nearly two per cent below the mint standard; and, of course, the price of gold bullion, estimated in this degraded currency, rose two per cent., or from £3:17:10½d, its mint price, to £4 per ounce. This, however, was too minute a difference to be taken into account in the ordinary business of buying and selling. And the possessors of coins fresh from the mint, or of full weight, not obtaining more produce in exchange for them than for the lighter coins, sent the former to the melting-pot, and sold them as bullion. But it is easy to see that this fusion would have been prevented had the coins been laden with a seignorage of two per cent. The heavy coins could not then have been melted without losing the value given them by the seignorage; and this being equal to the excess of the market price of bullion above the mint price, nothing would have been gained by the melters. Had the seignorage been less than two per cent., the average degradation of the coin, had it, for example, been only one per cent., all those coins whose value was not more than one per cent. degraded below their mint standard, might have been melted; but if the seignorage had exceeded two per cent., no coins would have been melted until the degradation had increased to the same or a greater extent.

This reasoning is bottomed on the supposition that the coins on which a seignorage is charged are not issued in excess. If they were, the above-mentioned consequences would not follow. Their too great multiplication might sink their value below that of bullion, and occasion their immediate fusion or exportation. So long, however, as the state only coins the bullion brought to the mint by individuals, there is little risk of this happening. No one, we may be pretty well assured, would carry bullion to that establishment, and pay the expenses of its coinage, unless the coins were thereby rendered so much more valuable than the unfashioned metal.

Were government to buy bullion, and coin money on its own account, it might, by proper attention, avoid all over-issue. Suppose the seignorage were two per cent., then any given weight of coins of the mint standard ought, provided the currency be not redundant, to purchase two per cent. more than the same weight of bullion. So long therefore, as this proportion is preserved between money and bullion, it shows that the proper supply of currency has been issued. If the value of the coins declines below this limit, too many of them must have got into circulation; and if, on the contrary, their value

¹ Seignorage, strictly speaking, means only the clear revenue derived by the state from the coinage. But it is now commonly used to express every deduction made from the bullion brought to the mint to be coined, whether on account of duty to the state, or of the expense of coinage (properly *brassage*). We always use the phrase in its more enlarged sense.

² Le Blanc, *Traité Historique des Monnoyes de France*, p. 90, ed. Amst. 1692.

Money. rises above it, the supply is too limited, and an additional quantity may be advantageously issued.

It must not, however, be concealed, that if it were attempted to charge a high seignorage, it would be extremely difficult, or rather quite impracticable, to limit the supply of coins. The inducement to counterfeit money would, under such circumstances, be very greatly increased, while the chances of detection would be very much diminished. It would not then be necessary, to make the counterfeiting of coins profitable, that they should be manufactured of base metal. The saving of a heavy charge on account of seignorage might of itself afford a sufficient profit; and this would be derived, though the metal contained in the forged coins were of the standard purity. But though it might, for this reason, be impossible, or very difficult, to limit the supply of currency, and consequently to sustain its value, were any thing like an exorbitant seignorage charged, the same difficulty would not stand in the way of a moderate seignorage. To be carried on the business of counterfeiting must yield a premium sufficient to indemnify the forgers for the risks and odium to which they are exposed. A seignorage insufficient to do this would not encourage the issue of counterfeit coins. And though it might be difficult to form any very precise estimate of the amount of the premium referred to, it would not probably be under two or three per cent.¹

In his evidence before the Lords' Committee in 1819, Mr Mushet stated that, with the improved machinery in use in the mint, gold coin could be manufactured for about 10s. per cent.² And the manufacture of the silver coin might then, we believe, be taken at about three times as much, or at one and a-half per cent. It appears from an account given in the report published in 1849 (p. 86), of the commissioners appointed to inquire into the constitution, &c., of the mint, that the expense of coining, at an average of the eleven years ending with 1848, amounted, exclusive of law expenses, to £1:5s. 3½d. per cent. The total amount coined during this period was £38,275,486, of which £34,877,664 was gold, £3,329,716 silver, and £68,103 copper. It is said to be very difficult to distinguish exactly the separate cost of coining the different metals. There can, however, be little doubt that the changes lately introduced into the mint will effect a very considerable saving in the expense of coining; and the probability is, that in future it will be under one per cent. on the average value of the total coins issued. In France the procedure at the mint has been so much perfected that the expense of coining gold has been reduced to six fr. on 3,100 fr. or to 0.193 per cent., and that of silver to 75 cent. per 100 fr., or ¾ per cent.³ In Russia the gold costs 0.85, and the silver 2.95 per cent.⁴

Notices of
seignorage
in Eng-
land.

The precise period when a seignorage began to be charged upon English silver coins has not been ascertained. It must, however, have been very early. Ruding mentions, that in a mint account of the 6th Henry III., one of the earliest he had met with, the profit on £3898, 0s. 4d. of silver coined at Canterbury, is stated to be £97:9s., being exactly 6d. a-pound, of which the king had £60:18:3½d., and the bishop the residue.⁵ In the 28th Edward I., the seignorage amounted to 1s. 2½d. per

pound, 5½d. being allowed to the master of the mint, to indemnify him for the expenses of coining, and 9d. to the crown as its profit. Henry VI. increased the master's allowance to 10d. and 1s. 2d., and the king's to 1s. and 2s. In the reign of Edward IV., the seignorage varied from 4s. 6d. to 1s. 6d. It was reduced to 1s. in the reign of Henry VII.; but was prodigiously augmented in the reigns of his successors, Henry VIII. and Edward VI., whose wild and arbitrary measures produced, as will be afterwards shown, the greatest disturbance of the currency. During the lengthened reign of Elizabeth, the seignorage varied from 1s. 6d. to 2s. per pound; at which sum it continued, with very little variation, until the 18th of Charles II. (1666), when it was remitted.

From this period down to 1817, no seignorage was charged on the silver coin; but a new system was then adopted. Silver having been underrated in relation to gold in the mint proportion of the two metals fixed in 1718, heavy silver coins were withdrawn from circulation, and gold only being used in all the larger payments, it became, in effect, what silver had formerly been, the standard of the currency. The Act 56th Geo. III. cap. 68, regulating the present silver coinage, was framed not to interfere with this arrangement, but so as to render silver entirely subsidiary to gold. For this purpose it was made legal tender to the extent of 40s. only; and 66s. instead of 62s. are coined out of a pound troy, the 4s. being retained as a seignorage, which, therefore, amounts to 6½ per cent. The power to issue silver is exclusively in the hands of government; who may, by not throwing too much of it into circulation, prevent its fusion, until the market price of silver rise above 5s. 6d. an ounce.

This arrangement was censured in the debates on the resumption of cash-payments in 1819. It was contended that the over-valuation of silver with respect to gold would make debtors use it in preference in discharging their debts, and that the gold coins would be melted or exported. The result has shown that this opinion was erroneous. Debtors cannot discharge their debts by silver payments; for, as seen above, it is legal tender for 40s. only; and no creditor can be compelled, or would be disposed to take it in payment of a larger debt, except at its real value.⁶

In the 18th of Edward III., the period when we begin to have authentic accounts of the gold coinage, a pound troy of gold bullion was coined into florins, of the value of £15. Of this sum, only £13:16:6 was given to the party who brought the bullion to be coined, £1:3:6 being retained as seignorage, of which 3s. 6d. went to the master, and £1 to the king. But it appears, from the mint indentures, that the seignorage on the coinage of nobles for the same year, amounted to only 8s. 4d. And, from this remote period to the accession of the Stuarts, with the exception of the coins issued in the 4th and 5th Edward IV., and the 34th, 36th, and 37th Henry VIII., the total charge of coining a pound weight of gold bullion seldom exceeded 7s. or 8s. money of the time. In the 2d James I., a pound weight of gold bullion was coined into £40:10s.; a seignorage of £1:10s. being deducted; 6s. 5d. of which went to the master, and £1:3:7 to the crown. The seignorage on gold was remitted at the same time (18th Charles II.)

Money.

⁶ Those who wish for a farther elucidation of this subject, may refer to Mr Mushet's evidence in the *Appendix to the Lords' Report on the Expediency of the Banks resuming Cash-payments*, where it is discussed at great length, and in a very able manner.

Money. with the seignorage on silver, and has not since been revived.¹

It appears from the official accounts, that during the ten years ending with 1855, the sum of £53,871,063 was coined at the mint into gold coins. If we estimate the cost of this coinage, including the loss on the old worn coins brought to the mint to be recoined, at 12s. per cent., it will amount to about £323,226. But two-thirds, probably, of this expense would have been rendered unnecessary, had a low seignorage of 2 per cent. been charged during this period; at the same time that it would have yielded a revenue of nearly $1\frac{1}{2}$ per cent. on the sums that were coined.

It is needless, after what has been previously stated, to dwell at any greater length on the futility of the practice of issuing coins free of expense to be exported or melted, as the case may be. It is the sieve of the Danaids over again. We might, on the same principle, supply natives and foreigners with plate *ad libitum* at the price of the bullion, making them a present of the workmanship. Whatever may be thought of the policy of making coins yield a revenue, there can be no reasonable doubt that they should, at all events, be charged with the expense of coinage.

As the regulation of the seignorage, when it did exist, depended entirely on the will of the sovereign, we need not be surprised at the variations in its amount, or that it should have fluctuated according to the necessities and caprices of succeeding princes. It was, indeed, hardly possible that it should have been otherwise. Our ancestors were ignorant of the principle, by a strict adherence to which the imposition of a considerable seignorage can alone be rendered advantageous. They considered it as a tax which might be increased and diminished at pleasure. And, far from taking any steps to limit the quantity of coin in circulation, so as to maintain its value, they frequently granted to corporate bodies, and even to individuals,² the privilege of issuing coins, not subject to a seignorage. No wonder, therefore, that it should have been considered as a most unjust and oppressive tax, and that its abolition should have been highly popular.

Remedy or
there.

Besides the revenue arising from the seignorage, our kings formerly derived a small revenue from the *remedy* or *shere*. It being found all but impossible to coin money corresponding in every particular of weight and purity with a given standard, a small allowance is made to the master of the mint, whose coins are held to be properly executed, provided their imperfections, whether on the one side or the other, do not exceed this allowance, or remedy. Its amount, from the reign of Edward III. down to 1816, was generally about one-eighth part of a carat, or 30 grains of pure gold per pound of gold bullion, and two pennyweight of pure silver per pound of standard silver bullion. In 1816, the remedy for gold coins was fixed at 12 grains per pound in the weight, and 15 grains per do. in the fineness; that for silver being, at the same time, reduced a half.

It does not appear that our princes derived any con-

siderable advantage from the *remedy* previously to the reign of Elizabeth. But she, by reducing the master's allowance for the expense of coinage from 1s. 2d. to 8d., obliged him to come as near as possible to the lowest limit allowed by the remedy. Had the coins been delivered to those who brought bullion to the mint by weight, the queen, it is plain, would have gained nothing by this device. But, in the latter part of her reign, and the first seventeen years of that of her successor, James I., they were delivered by *tale*, so that the crown saved, in this way, whatever additional sum it might otherwise have been necessary to pay the master for the expenses of coinage. In the great recoinage in the reign of William III., the profit arising from the remedy amounted to only 8s. on every hundred pounds weight of bullion; and the coinage is now conducted with so much precision, and the coins issued so near their just weight, that no revenue is derived from this source.

The continental princes have, we believe without any exception, charged a seignorage on the coinage of money. In France, this duty was levied at a very early period. By an ordonnance of Pepin, dated in 755, a pound of silver bullion is ordered to be coined into twenty-two pieces, of which the master of the mint was to retain one, and the remaining twenty-one were to be delivered to the merchant bringing the bullion to the mint.³ There are no means of ascertaining the amount of the seignorage taken by the successors of Pepin, until the reign of Saint Louis (1226-1270), who coined the *marc* of silver into 58 sols, while he only delivered 54 sols 7 deniers to the merchant: at this period, therefore, the seignorage amounted to a sixteenth part of the marc, or to $6\frac{1}{4}$ per cent. It was subsequently increased or diminished without regard to any fixed principle. In the great recoinage in 1726, it amounted, on the gold coin, to $7\frac{1}{8}$ per cent., and to $5\frac{1}{4}$ per cent. on silver. In 1729, the mint prices, both of gold and silver, were augmented, and the seignorage on the former reduced to $5\frac{1}{2}$ per cent., and on the latter to $4\frac{1}{2}$ per cent. A farther reduction took place in 1755 and 1771, when the seignorage on gold was fixed at $1\frac{1}{2}$ per cent., and on silver at $1\frac{1}{4}$ per cent.⁴ At the Revolution the seignorage was converted into a brassage, being reduced nearly to the expense of coinage.

SECT. IV.—Expense of a Currency consisting of the Precious Metals.

A moderate seignorage has but an inconsiderable effect in reducing the expense of a metallic currency. This, which is much greater than is generally imagined, is not occasioned by the coinage, which is comparatively trifling, but by the value of the gold and silver vested in coins. If, for example, the currency of the United Kingdom consisted wholly of gold, it would amount to at least eighty millions of sovereigns; and if the customary rate of profit were 6 per cent., it would cost £4,800,000 a-year; for, were this eighty millions not employed as money, it would be employed in branches of industry, in which, besides affording wages to numerous individuals,

Estimates
of the ex-
pense of a
metallic
currency.

¹ In the tables annexed to this article, the reader will find a detailed account of the amount of the seignorage and its fluctuations in different periods.

² Ruding's *Annals of the Coinage*, vol. i. p. 185. When the right of seignorage was abolished, there was a pension, payable out of the profits derived from it, granted under the great seal, for twenty one years, to Dame Barbara Villiers, which the legislature ordered to be made good out of the coinage duties imposed by that act. (See Ruding, *in loco citato*, and Leake's *Historical Account of English Money*, 2d edit., p. 356.)

³ Le Blanc, p. 87.

⁴ Necker, *Administration des Finances*, (tom. iii. p. 8).—Dr. Smith has stated (*Wealth of Nations*, p. 21), on the authority of the *Dictionnaire des Monnoies*, of Abot de Bazinthen, that the seignorage on French silver coins, in 1775, amounted to about eight per cent. The error of Bazinthen has been pointed out by Garnier, in his translation of the *Wealth of Nations*.

Money. it would yield 6 per cent., or £4,800,000 a-year, nett profit to its possessors. And this is not the only loss. The eighty millions would not merely be withheld from the great work of production, and the country deprived of the revenue derived from its employment, but it would be perpetually diminished. The wear and tear of coins is by no means inconsiderable; and supposing the expenses of the coinage were defrayed by a moderate seignorage, the deficiency in the weight of the old worn coins, on their being called in to be recoined, falls on the public. There is, besides, a constant loss from shipwreck, fire, and other accidents. When due allowance is made for these causes of waste, it may not, perhaps, be too much to suppose that a country which had eighty millions of gold coins in circulation, would have annually to import and coin the hundredth part of this sum, or £800,000, to maintain its currency at its proper level.

Thus it appears probable that, were the customary rate of profit in the United Kingdom 6 per cent., it would cost £5,600,000 a-year to maintain eighty millions of gold coins in circulation. A reduction of the rate of profit would, no doubt, proportionally reduce the amount of this expense; but the reduced expense might still bear the same proportion to the total income of the country that the higher expense did, and if so, the cost of the currency would not be at all diminished. The case of France furnishes a striking example of the heavy charges attending the general use of a metallic currency. The gold and silver currency of that kingdom has been estimated by M. Fould at 2200 millions fr., and by others at 2500 millions.¹ Now, supposing the lowest estimate to be the more correct, and taking the rate of profit at 6 per cent., this currency must cost France a hundred and thirty-two millions fr. a-year, exclusive of the wear and tear and loss of the coins, which being taken, as before, at the hundredth part of the entire mass, will make the whole annual expense amount to a hundred and fifty-four millions fr., or to about *six millions* sterling. This heavy expense forms a very material deduction from the advantages resulting from the use of a currency consisting entirely of the precious metals, and has doubtless been a chief cause why all civilized countries have endeavoured to fabricate a portion of their money of less valuable materials. It has not, however, been the only cause. It is obvious, were there nothing but coins in circulation, that the conveyance of large sums from place to place would be a very laborious process; and that even small sums could not be conveyed without considerable difficulty. Of the substitutes, calculated alike to save expense and to lessen the cost of carriage, paper is in every respect the most eligible, and has been by far the most generally adopted. By using it instead of gold, we substitute the cheapest for the most expensive currency, and enable the public to exchange whatever coins the employment of paper may render superfluous, for raw materials or manufactured goods, by the use of which its wealth and enjoyments are increased. It is also transferred with the utmost facility. Hence, since the introduction of bills of exchange, most great commercial transactions have been adjusted by means of paper only, and it also is very extensively used in the everyday business of society.

SECT. V.—How Paper is substituted for Coins, and its value maintained.

In all advanced societies, pecuniary engagements are usually reduced to writing. This secures alike the

debtors and creditors; and obviates most part of the differences which are so very apt to arise when the terms of contracts are not distinctly specified. But it is an obvious resource for such individuals as happen to possess the written obligations or bonds of others, to transfer them when occasion requires to their debtors. And it is probable that no very lengthened period would elapse after they had been employed in this way till persons in whose wealth and discretion the public had confidence, would begin to issue their notes to pay certain sums in such a form that they might readily pass from hand to hand in ordinary pecuniary dealings. But as these notes or promises, though they cost the issuers next to nothing, must be paid when presented, or at some specified date, they would not be issued, or given away, except to those who engaged to repay them with a premium or interest, the amount of which would, of course, belong to and be a source of profit to the issuers.

Suppose, for example, that a capitalist issues a promissory note for £1000. This he does by advancing it to an individual in whose solvency he has confidence, or who has given him security for its repayment with interest. In point of fact, therefore, the issuer has exchanged his promissory note to pay £1000 for an obligation of equal amount, bearing the current rate of interest; and so long as the note, the intrinsic worth of which cannot well exceed a sixpence, remains in circulation, he will, supposing interest to be 5 per cent., receive from it a revenue of £50 a year. The business of bankers who issue notes is conducted on this principle. They could make no profit were they obliged to keep dead stock or bullion in their coffers equal to the amount of their notes in circulation. But if they be in good credit, a fourth or a fifth part of this sum will perhaps be sufficient. And their profits, after the expenses of their establishments, including the manufacture of their notes, are deducted, will be measured by the excess of the profit derived from their notes in circulation, over what they might derive from the employment of the stock kept in their coffers to meet the demands of the public.

All descriptions of notes, whether they are issued by individuals, or corporations, that are made payable in coin on demand, or at fixed periods, cease to circulate as soon as a suspicion begins to be generally entertained of the solvency of the issuers, or of their ability to make good their engagements. But paper-money, meaning thereby notes not payable on demand, but which are, notwithstanding, legal tender, is not affected by a want of credit. It may be depreciated through excess, but by nothing else. It has no intrinsic worth, and is not the representative of anything in particular. Its value, as already shown, is entirely dependent on the extent to which it is issued. From 1797 down to 1821, Bank of England notes, though not payable in gold, were *de facto* legal tender, and their value was determined by the principle now stated, and by it only.

It has, however, been contended, that there is a material difference between the inconvertible paper issued by governments in payment of their debts, and that which is issued by a company like the Bank of England, in discount of approved bills. In regard to the former, it is admitted on all hands that its value may be depreciated from excess. But in regard to the latter, it has been argued, that this is impracticable; that its supply is limited by the legitimate wants of the public; and that being issued only in proportion to the demand in exchange for good and convertible securities, payable at specific and not very distant dates, it can neither be in excess nor depreciated.

Money.
Origin of paper money, and how its value is maintained.

¹ *Chevalier De la Monnaie*, p. 326.

Money.

The apologists of the Restriction Act of 1797 endeavoured to show, by reasonings founded on assertions like these, that Bank of England notes were not depreciated during the suspension of cash payments. But though their fallacy, which is sufficiently obvious, was demonstrated over and over again by the authors of the Bullion Report, by Messrs. Ricardo, Blake, Huskisson, and others, and has been acknowledged by the legislature and the public, such is the vitality of error, or the inveteracy of prejudice, that we have these assertions repeated in 1857 as if their accuracy neither had been nor could be questioned. And such being the case, it may be right shortly to re-state principles which have been frequently stated before, and which we had supposed might have been safely taken for granted.

Fallacy of this allegation.

It may be premised on entering on this discussion, that the demand for money is not like the demand for other things. A man may have enough of beef, of beer, of cloth, and of a great many articles; but of money he never can have what he would consider enough. An increase of money means an increase of riches, that is, of power and consideration, and the desire for these is altogether illimitable. Whether money consist of paper, or gold, or both, the demand for it will be alike great; and will wholly depend on the price or interest charged for loans, and not on the value of the money lent.

Demand for money depends on a comparison between interest and profit.

These statements are so obviously well-founded as hardly to require illustration. If an individual can borrow £1000, £10,000, or any greater sum, at 3, 4, or 5 per cent. interest, and if he can invest it so as to yield 4, 5, or 6 per cent. it is plainly for his advantage, and for that of every other person who may be similarly situated to borrow to an unlimited extent. And a company that issued inconvertible paper, and was consequently relieved from the necessity of keeping any unproductive stock or bullion in its coffers, might issue notes at a very low rate of interest, and if so, the demand for them would be proportionally great.

During the period from 1809 to 1815, both inclusive, the issues of Bank of England and the provincial banks were much greater than they had ever previously been, and their paper was at a heavy discount as compared with bullion. But owing to the interest charged by the banks (5 per cent.) being less than the market rate at the time, the parties applying for fresh discounts were constantly on the increase. It is in truth quite immaterial to such parties whether the issuers have, by issuing notes in excess, depressed their value as compared with gold, or have limited their supply, so as to keep them on a level with that metal. These circumstances are of primary importance to those whose incomes do not vary with variations in the value of money; but as prices rise and fall with its increase or diminution, they have little or no influence over merchants and tradesmen, who are the principal applicants for discounts. A, who presents a bill for £500 or £1000 to a bank for discount, has received it, if it have grown out of a real mercantile transaction, in payment of goods which were worth £500 or £1000 money of the day; and it is this sum which he wishes to obtain by discounting the bill. Had the value of money been different, the price of the goods, and consequently, the sum in the bill, would have differed proportionally. Its market value at the moment is the only thing attended to in these transactions. And it is quite the same when the bills are for accommodation purposes. It matters not whether the notes given for them are worth 10s. or 20s. In the one case the bills would be nominally twice

as great as in the other, but there would be no real difference between them. So long as the rate of interest charged for discounts or loans is under the market rate, the demands for money can never be supplied. In such case million after million may be issued. The value of the currency, if it consist of inconvertible paper, may be so reduced as to require £1 or £5 to purchase a quatern loaf; but the circumstance of its value being diminished in proportion to the increase of its quantity would render the demand for additional supplies as great as ever.

It is plainly, therefore, the merest drivelling to talk about the demands for money being limited by the wants of the public. These wants, like the avarice of the miser, or the thirst of the dropsical patient, are altogether boundless. They have no possible limit, and would be as great after 100 or 1000 millions of notes or sovereigns had been issued as after an issue of 10 or 20 millions.

Money.

But when a currency consists of gold, or partly of gold and partly of paper immediately convertible into gold, it contains within itself a principle by which its over-issue is corrected. In that case, the issue of 100,000 or 1,000,000 sovereigns, and of 100,000 and 1,000,000 £1 notes, has precisely the same effect. Paper is not depreciated as compared with gold, for the latter may at pleasure be obtained for the former; but the whole currency, gold as well as paper, becomes redundant, or is depreciated, as compared with that of other countries in which there has been no over-issue. And as gold is everywhere in demand, and the expense of its conveyance from one state to another seldom exceeds one or two per cent., it follows, that if the currency be depreciated by over-issue to any greater extent than this, the exchange will become unfavourable, and gold will begin to be exported. And if, in such circumstances, the issuers of paper do not, by withdrawing a portion of their notes from circulation, raise the value of the currency and restore the exchange to par, the drain for bullion will undoubtedly continue till they have been deprived of their last sovereign, and are compelled to stop payments.

Limit of depreciation in a gold or mixed currency.

The currency may become redundant from various causes exclusive of the over-issue of paper, such as the greater economy of its issue by means of improved banking, the occurrence of bad harvests, the prevalence of discredit or the scarcity of money in countries with which we are commercially connected, and so forth. But however it may originate, the fact of the exchange being unfavourable, and an efflux of gold taking place, shows that the currency is in excess, and should be diminished.

We are aware that this conclusion has been denied in the case of an unfavourable exchange occasioned by a bad harvest. But, there is no room or ground for any such denial. The fact that a harvest is bad, that is, that the produce to be circulated by the intervention of money is diminished by rendering the latter redundant and reducing its value, makes it be exported to countries where its value is greater. And its exportation, by raising its value here, and reducing that of other articles, is the surest means of increasing their exportation and reducing the foreign demand for bullion to a minimum.

Though consistent with the soundest theory, this is not mere theoretical reasoning. The issues of the Bank of England were for about a century previously to 1797, limited in the way now explained; and though, during that lengthened period, the occasional efflux of gold showed that the currency was in excess, there was no discrepancy between the value of gold and paper.¹ Since

¹ Previously to the recoinage of gold in 1774, the market price of gold exceeded its mint price by about 2½ per cent. But this was not a consequence of gold or paper being in excess, but of the gold coins being worn to that extent. On the new coins being issued, the discrepancy between the mint and market price of gold disappeared.

Money. 1821, the issues of the bank have been limited on the same principle. And it will be afterwards seen, that by neglecting to attend in 1825, and other occasions, to the unerring evidence afforded by the fall of the exchange of the currency being in excess, and requiring to be reduced, the bank was brought into the most serious difficulties.

No limit to the depreciation of inconvertible paper.

But there is no such check over the issues of inconvertible paper. It is legal tender only in the country in which it is issued. Abroad it has no such privilege, and is, consequently, worth nothing. Hence, if it be issued in excess, the surplus cannot, as in the case of gold, be removed or lessened by exportation. It is confined to the country of its birth; and there is nothing to sustain its value but the discretion of the issuers. And all experience shows that no dependence can be placed on a restraint of this sort. Even in England, where all matters connected with money are supposed to be comparatively well understood, the inconvertible paper of the bank was over-issued, so as to be, in 1814, at a discount as compared with gold, of no less than 25 per cent.¹ And it is probable that, but for the destruction of country bank paper, caused by the political events of the period, the over-issue and depreciation of bank-notes would have been carried still further. The fact is, that the power to issue inconvertible paper has never been conceded to any man, or set of men, without being abused, that is, without its being issued in excess. The re-enactment of the restriction Act of 1797, and making it perpetual, would have no influence over the value of paper, provided its quantity were not at the same time increased. But who can doubt that it would be increased? Such a measure would enable the Bank of England to exchange bits of engraved paper, not worth, perhaps, 5s. a quire, for as many, or the value of as many, hundreds of thousands of pounds. And is it to be supposed that the directors and proprietors should not avail themselves of such an opportunity to amass wealth and riches. If government enable a private gentleman to exchange a scrap of paper for an estate, will he be deterred from doing so by any considerations about its effect on the value of the currency? In Utopia we might, perhaps, meet with an individual influenced by such scruples; but if we expect to find him in England, we shall most likely be disappointed.

It thus appears to be essential that all notes, how much soever they may differ in other respects, should be payable in specie on demand. But it is not enough to enact a law of this sort. It is indispensable that effective measures should, at the same time, be adopted to ensure its being carried out; that is, to make certain that its provisions shall not be defeated by fraud, mismanagement, or any sort of contingency; but that coins shall always be obtainable at the pleasure of the holders of the notes which circulate in their stead.

SECT. VI.—*Whether Gold or Silver should be adopted as the Standard of the Currency, or whether it should consist of both.*

The relation of gold to silver subject to constant variation.

As the values of gold and silver perpetually vary, not only relatively to other things, but also to each other, it is impossible arbitrarily to fix them by mint regulations. Gold may now, or at any given period, be to silver as

13, or 14, or 15 to 1; but were sovereigns and shillings made exchangeable in that proportion, the discovery of a gold or silver mine of more than the ordinary degree of productiveness, or the discovery of any abridged process by which labour might be saved in the production of one of the metals, would disturb this proportion. And as soon as the mint valuation of the two metals ceases to correspond with that which they bear in the market, it becomes the interest of debtors to satisfy all claims upon them in the over-valued metal, which, consequently, is alone used in all considerable transactions.

The regulations under which gold and silver coins circulated in England previously to 1663, differed at different periods. In that year the guinea was first coined; and its value (though fixed by the mint regulations at the low rate of 20s. in silver), and the values of the other gold coins then in circulation, varied according to the fluctuations in the market values of gold and silver, the latter being then in effect the only legal tender. But, from a variety of causes—the principal being, perhaps, the very unsatisfactory state of the silver coin, gold began, under the Commonwealth, and in the reign of Charles II., to be used in preference to silver in large payments. Previously to the great recoinage of silver in the reign of William III. (1696-1699), the silver coins were so much worn and degraded, that the guinea passed current at from 28s. to 30s. After the recoinage, its value was very generally estimated, without any interference on the part of government, at 21s. 6d.; a valuation which was equivalent to a premium of 10d. in its favour, it being really worth only about 20s. 8d. of the new silver coins.

In consequence of this marked, though unintentional, preference of gold, the new silver coins immediately began to be exported; and, to stop their exportation, the value of the guinea was reduced, by proclamation in 1717, from 21s. 6d., at which it had been fixed by custom, to 21s., both metals being made legal tenders in that proportion, or in the ratio of 1 lb. gold to 15 $\frac{285}{384}$ lbs. silver. But notwithstanding this reduction, which was made pursuant to the advice of Sir Isaac Newton, the guinea was still over-valued as compared with silver. This excess was estimated at the time at about 4d. in the guinea, or 1 $\frac{3}{4}$ per cent.;² and as the value of silver compared with gold continued to increase for the greater part of last century, it afterwards became considerably greater; and this circumstance rendered it, as already stated, more and more the interest of all parties to pay in gold rather than in silver. Hence gold became in practice the only legal tender. And during the lengthened period, from 1717 down to 1816, no silver coins of the legal weight and purity would remain in circulation, but were either melted down, or exported to other countries, where they passed at their full value. In consequence, the silver currency consisted entirely of light, worn coins. But as it existed only in a limited quantity, it did not, according to the principle already explained, sink in its current value. Though degraded, it was still the interest of debtors to pay in gold. If, indeed, the quantity of debased silver had been very great, or if the mint had issued debased pieces, it might have been the interest of debtors to pay in such debased money; but its quantity being limited, it sustained its value, and gold was really the standard of the currency.

The mint regulations issued in 1717, continued in full force down to 1774, when it was enacted by the 14 Geo.

¹ Rather an indigestible fact for those who contend that bank notes, being issued in proportion to the demand, have not been depreciated from excess.

² *Liverpool On Coins*, pp. 68-85.

Over-valuation of gold made it be adopted as the standard in this country.

Money.

III., cap. 42, that silver coins should not be legal tender by tale for more than £25 in any one payment, but that standard silver should be legal tender to any amount in weight at the mint price of 5s. 2d. an ounce.¹ This act had not, however, as some have supposed, any effect in causing the general employment of gold as money in preference to silver. For, to use the words of Mr Ricardo, "it did not prevent any debtor from paying any debt, however large its amount, in silver currency fresh from the mint. That the debtor did not pay in this metal was not a matter of chance, nor a matter of compulsion, but wholly the effect of choice. It did not suit him to take silver to the mint, but it did suit him to take gold hither. It is probable that, if the quantity of this debased silver in circulation had been enormously great, and also a legal tender, that a guinea would have been, as in the reign of William III., worth thirty shillings; but it would have been the debased shilling that had fallen in value, and not the guinea that had risen."²

Over-valuation of silver made it be adopted as the standard in France; but a change in the opposite direction is now taking place.

In France, a different valuation of the precious metals produced a different effect. The louis d'or, which, previously to the recoinage of 1785, was rated in the mint valuation at 24 livres, was really worth 25 livres 10 sols. Those, therefore, who chose to discharge the obligations they had contracted, by payments of gold rather than of silver, plainly lost 1 liv. 10 sols on every sum of 24 livres. In consequence, very few such payments were made, gold was nearly banished from circulation, and the currency of France became almost entirely silver.³ In 1785, a sixteenth part was deducted from the weight of the louis d'or, and after that period the value of the precious metals, as fixed in the French mint, more nearly corresponded with the proportion which they bore to each other in the market. Indeed, it was stated, before a committee of the House of Commons in 1819, that the difference between the mint and market proportions of gold and silver at Paris in 1817 and 1818, had not exceeded from one-tenth to one-fourth per cent. There was, however, no reason to presume that this coincidence, which must have been in a great degree accidental, could long be maintained under any arbitrary system, and it has recently been wholly set aside. The great increase in the supplies of gold from California and Australia, coupled with the extraordinary demand for silver in India and China, having raised the value of the latter, as compared with that of the former, gold has come into very extensive use as money in France. There seems, indeed, to be little doubt that it will very speedily be as generally used there as in England. Large amounts of French silver currency have been exported; and it will, most likely, become subsidiary to gold, and be employed only in making small payments.

To ensure the indifferent use of gold and silver coins in countries where they are both legal tender, their mint values would require to be every now and then adjusted, so as to correspond with their real values. But as this would obviously be productive of much trouble and inconvenience, the preferable plan undoubtedly is to make only one metal legal tender, and to allow the worth of the other to be adjusted by the competition of the sellers and buyers.

The absurdity of employing two metals as legal tender,

or as a standard of value, was unanswerably demonstrated by Locke and Harris, and has been noticed by every subsequent writer. But so slow is the progress of improvement, that it was not till 1816 that it was enacted that gold should be in law, what it had long been in fact, the only legal tender for sums of 40s. and upwards. And a seignorage being then also charged upon silver, it has become entirely subordinate to gold, and is little used except in payments of fractional parts of a pound, or rather of 10s.

Whether, however, gold should have been adopted as the standard of exchangeable value in preference to silver, is a question not so easy of solution, and on which there has been a great diversity of opinion. Locke, Harris, and Ricardo are of opinion that silver is better fitted than gold for a standard; whilst Smith, though he has not explicitly expressed himself, appears to think that gold should be preferred. This latter opinion has been supported by Lord Liverpool, in his very able work "On the Coins of the Realm." And his reasonings having received the approbation of Parliament, and gold having been for a lengthened period the only legal tender, all attempts to alter this arrangement ought to be opposed.

Gold the preferable standard.

The late extraordinary increase in the supply of gold has led many persons to anticipate great inconvenience from the fall which may be expected to take place in its value. But, supposing that this fall should, as appears most probable, take place in the end, there is no ground for concluding that it will be brought about otherwise than by slow degrees; and if so, it will not occasion any injurious disturbance. About 140 or 150 years elapsed from the discovery of America before the influx of bullion from the new into the old world produced its full effect. And it is doubtful, considering the vastly increased field for the employment of gold and silver, whether the supplies from California and Australia will speedily exercise any very material influence. We shall elsewhere endeavour to show that a gradual fall in the value of gold would, in a public point of view, be advantageous rather than otherwise.⁴

Whether gold or silver be adopted as the standard of the currency, does not affect its total cost or value; for the quantity of metal employed as money, or the quantity of metal for which paper is the substitute, is always inversely as the value or cost of such metal. When silver is the standard, fourteen or fifteen times more of it than of gold is required; or, which is the same thing, if the denomination of a pound be given to any specific weight of gold or silver, fourteen or fifteen times more of such silver pounds will be required to serve as currency, fourteen or fifteen to one being about the proportion which gold bears in value to silver. Hence the expense of a gold or silver currency is identical. Gold being too valuable, in proportion to its bulk, to be coined into pieces of the value of a shilling or a sixpence, the subordinate currency necessary in small payments should be over-valued, and issued only in limited quantities, as is the case with the existing silver coins.

Were a seignorage charged on the gold coins, paper, it is obvious, might be depreciated to its extent before it would be the interest of the holders to demand coin

¹ Being intended as an experiment, this act was limited to the 1st May 1776. But not being found to be productive of any inconvenience, it was prolonged by other temporary acts. It was, however, suffered accidentally to expire in 1783, and was not renewed till fifteen years after, in 1798. And yet, despite the extremely degraded state of the silver coin, very few instances occurred during this lengthened period of its being offered in payment of any considerable sum.

⁴ See Art. PRECIOUS METALS in this work.

A double standard absurd.

Money. for the purpose of exportation, and consequently before the check of specie payments would begin to operate. But, even with a seignorage, all risk of paper being depreciated, might be obviated by making it obligatory on the bank to pay her notes, either in bullion, at the mint price of £3:17:10½d. an ounce, or coin, at the pleasure of the holder. A regulation of this kind could not be justly considered as imposing any hardship on the bank; for no bullion would be demanded from her, except when, by the issue of too much paper, its value had been sunk below the standard.

Standard
of money.

SECT. VII.—Standard of Money. *Duodecimal and Decimal systems of dividing Coins. Degradation of Coins in Rome, France, Great Britain, and other countries. Effects of this degradation.*

By the standard of money is meant the degree of the purity or fineness of the metal of which coins are made, and the quantity or weight of such metal in them. A pound troy, or twelve ounces of the metal in English silver coins, contains 11 ounces 2 dwts. fine silver, and 18 dwts. alloy. And this standard pound, or pound sterling, is coined into 66 shillings; which, consequently, contain $\frac{3}{4}$ parts of $\frac{1}{12}$ of a pound troy, or 1614.545 grains fine silver. From the 43 of Elizabeth down to 1816, when the 56th Geo. III. cap. 68, imposing a seignorage of about six per cent. on the silver coin, was passed, the pound weight of standard silver bullion was coined into 62 shillings. All English silver coins have been coined out of silver of 11 oz. 2 dwts., fine, from the Conquest to this moment, excepting for a period of sixteen years, from 34th Henry VIII. to the 2d Elizabeth.

Purity of
English
coins.

The purity of gold is not estimated either in Great Britain, or in most other European countries, by the weights commonly in use, but by an Abyssinian weight called a *carat*.¹ The carats are subdivided into four parts, called grains, and these again into quarters; so that a *carat grain*, with respect to the common divisions of a pound troy, is equivalent to $2\frac{1}{2}$ penny-weights. Gold of the highest degree of fineness, or pure, is said to be 24 carats fine. When gold coins were first struck at the English mint, the standard of the gold in them was 23 carats $3\frac{1}{2}$ grains fine, and one-half grain alloy; and so it continued, without any variation, till the 18th Henry VIII., when a new gold standard of 22 carats fine, and two carats alloy was introduced. The first of these was called the old standard; the second, the new standard or crown gold, because crowns, or pieces of the value of five shillings, were first coined of this new standard. Henry VIII. made his gold coins of both standards; and this practice was continued by his successors till 1633. But from the latter period to the present, gold coins have been invariably of the new standard, or crown gold. Some coins of the old standard continued to circulate till 1732, when they were forbidden to be any longer current.²

The standard of our present gold coins is, therefore, eleven parts of fine gold, and one part of alloy. The pound troy of such gold is divided into $46\frac{8}{11}$ sovereigns, each of which ought, consequently, when fresh

from the mint, to weigh $\frac{1}{46}\frac{8}{11}$ of twelve ounces, or five dwts. $3\frac{1}{8}\frac{1}{8}$ grains standard gold, or four dwts. $17\frac{1}{11}\frac{1}{14}$ grains pure gold.

The alloy in coins is reckoned of no value. It is allowed, to save the trouble and expense that would be incurred in refining the metals so as to bring them to the highest degree of purity; and because, when its quantity is small, it renders the coins harder, and less liable to be worn or rubbed. If the quantity of alloy were considerable, it would lessen the splendour and ductility of the metals, and would add too much to the weight of the coins.

The pound sterling, represented by the sovereign, is the integer or unit of currency in England; it being subdivided into twenty shillings, each shilling into twelve pence, and each penny into four farthings. Latterly, however, this system, notwithstanding its many recommendations, has been a good deal objected to; and various proposals have been made for substituting in its stead a coinage on the decimal plan. Most part of these proceed on the assumption that the pound is to be maintained as the integer, it being subdivided into tenths, hundredths, and so on, as in the French coinage. But there would be no little difficulty in carrying out a project of this sort. Shillings (two to be called a florin) might be continued in the new coinage; but pence and farthings would have to be discarded. This is evident from the following comparison:—

At present £1 = 20 shillings = 240 pence = 960 farthings.
Proposed plan £1 = 10 fl. (each = 2 sh.) = 100 cents = 1000 mills.

Now, as cents and mills are neither equivalent to, nor whole multiples of pence and farthings, it would be impracticable accurately to adjust to the new scale the prices of such articles, duties, or services as are wholly or partly rated in pence and farthings. It is evident, for example, inasmuch as mills would be four per cent. less valuable than farthings, that those retailers, of whom there are many, who supply the poor with small quantities of the various articles priced in farthings, could not accept mills in their stead without incurring a heavy loss. And if, as is most likely, they attempted to right themselves by charging two mills for a farthing, and three cents for a penny, serious injury would be inflicted on those who dealt with them. But, suppose that this difficulty is got over, and that prices are one way or other adjusted to the new scale, the question remains, Would the change be advantageous? And, despite all that has been alleged in its favour, we are satisfied that it would not.

The object of coins is twofold, viz., 1st., to serve as standards of value, and, 2d., to facilitate exchanges. With respect to the first of these functions, it is of no consequence how coins are subdivided, the grand requisite being that their weight and purity should be preserved inviolable, and that the substitutes used in their stead should be immediately convertible into them. In their second function, or as instruments for facilitating exchanges, coins are very little used in transactions of £5 and upwards, these being mostly settled by the intervention of notes and cheques. But coins, especially shillings, pence, and farthings, are of universal use in

¹ The carat is a bean, the fruit of an Abyssinian tree, called Kura. This bean, from the time of its being gathered, varies very little in its weight, and seems to have been, in the earliest ages, a weight for gold in Africa. In India it is used as a weight for diamonds, &c. (Bruce's *Travels*, vol. v. p. 66.)

² *Liverpool On Coins*, p. 27.

Money. retail dealings; and these form the vast majority, nineteen twentieths or more of the ordinary business of society. Hence, if a system of coinage be well fitted for such dealings, it matters little whether it be equally well suited to those large transactions in which coins are seldom or never employed. It is easy, however, to see that shillings, or coins of twelve parts, are much better adapted to the retail trade than florins or coins of ten parts. The former are divisible without fractions by six, four, three, and two, whereas the latter are divisible only by five and two. We are constantly buying or dealing in the thirds, the quarters, and so on of different articles; but with a decimal division of the integer, this would sometimes be impracticable and sometimes difficult; for we could not pay the price of a third, two thirds, or a sixth of anything, nor could we pay for a fourth, an eighth, &c., without introducing inconvenient fractions. In so far, therefore, as retail transactions are concerned, a duodecimal is at once seen to be decidedly preferable to a decimal scale. The superiority of the latter consists, if at all, in its affording greater facilities for the keeping of books and accounts. And this advantage, supposing it to be real, is of trivial importance compared with the other. Few individuals keep books or accounts, whereas everybody, the rich as well as the poor, but especially the latter, have innumerable, daily, and almost hourly transactions, which being adjusted *viva voce*, are concluded by the delivery of small coins. Our readers may not, perhaps, be generally aware of the fact that a considerable portion of the tea and sugar sold in London and other great towns is retailed in ounces, in the payment of which farthings are frequently required. Tobacco and snuff are, also, almost wholly disposed of in this way, and it is partially or wholly the case with other important articles.

Unless, therefore, the interests of the many be sacrificed, without scruple or equivalent, to the interests of the few, the existing coinage regulations must be upheld. The advantages on their side are quite preponderating. Nothing can be better suited than the duodecimal scale to the exigencies of the great bulk of society, whereas the decimal scale is, at best, suited only to what is a comparatively small body of clerks and accountants.

And, even in the case of the latter, it is the easiest thing imaginable for those who prefer keeping books and accounts on the decimal plan to do so at present. The keepers of such books would soon come to recollect the decimals for all the principal subdivisions of a pound. And, were a table of such equivalents affixed to their desks, they might, when they happened to be at fault, by looking into it, find the desired figures at a glance.

Besides being best fitted to secure the principal advantages to be derived from the use of coins, our present system has the further and most important recommendation that it is in operation, and that all classes, even those who can neither read nor write, are familiar with its divisions, and employ it with the greatest ease and expedition. It would be extremely difficult to subvert an established system of this sort to make room for one of less easy application, abounding in outlandish terms, and to which every body would be a stranger. Even in France, where the most sweeping of revolutions paved the way for the decimal system, it has had to be materially modified, and is not yet fully introduced.

Money. But the change, how inconvenient soever, might be submitted to, were it certain to be in the end advantageous. When, however, the reverse is the case, when the change would be alike undesirable and inconvenient, it would be worse than foolish to disturb the existing arrangements.¹

Having thus ascertained what the standard of money really is, and how coins may be best divided, we proceed briefly to inquire into the effects produced by the depreciation of the latter. This is a very important inquiry, both in a practical and historical point of view.

Directly to alter the terms of the contracts between individuals, would be too barefaced and tyrannical an interference with the rights of property, to be tolerated. Those, therefore, who endeavour to enrich one part of society at the expense of another, find it necessary to act with caution and reserve. Instead of changing the stipulations in contracts, they have resorted to the ingenious device of changing the standard by which these stipulations are adjusted. They have not said, in so many words, that ten or twenty per cent. should be added to, or deducted from, the debts and obligations of society, but they have, nevertheless, effected this by making a proportional change in the value of money. Men, in their bargains, do not, as has been already seen, stipulate for signs or measures of value, but for real equivalents. Money is not merely the standard by a comparison with which the values of commodities are ascertained; it is also the equivalent, by the delivery of a specified amount of which the stipulations in most contracts and engagements may be discharged. It is plain, therefore, that it cannot vary without affecting these stipulations. Every addition to its value makes a corresponding addition to the debts of the state and of individuals; whereas every diminution of its value makes a corresponding diminution of these debts. Suppose that, owing to an increase in the cost of gold and silver, or in the quantity of bullion contained in coins of the same denomination, the value of money is raised ten per cent.: it is plain that this will add ten per cent. to the various sums which one part of society owes to another. Though the nominal rent of the farmer, for example, continues stationary, his real rent is increased. He pays the same number of pounds, or livres, or dollars, as formerly; but these have become more valuable, and require, to obtain them, the sacrifice of a tenth part more corn, labour, or other things, the value of which has remained stationary. On the other hand, had the value of money fallen ten per cent., the advantage would have been wholly on the side of the farmer, who would have been entitled to a discharge from his landlord, when he had paid him only nine-tenths of the rent really bargained for.

But, though it be thus obviously necessary, to prevent a pernicious subversion of private fortunes, and the falsifying of all precedent contracts, that the standard of money, when once fixed, should be maintained inviolate, there is nothing which has been so frequently changed. We do not now allude to variations in the value of bullion itself, against which it is impossible to guard, but to variations in the quantity of bullion contained in the same nominal sums of money. In almost every country, debtors have been enriched at the expense of their creditors. The necessities, or the extravagance of

¹ For a further and complete exposition of this question, see Lord Overstone's *Queries annexed to the Report of the Commissioners on Decimal Coinage*.

Money.

governments, have forced them to borrow. And to relieve themselves of their encumbrances, they have almost universally had recourse to the disgraceful expedient of degrading or enfeebling the coin; that is, of cheating those who had lent them money, and of enabling every private debtor in their dominions to do the same by his creditors.

The ignorance of the public in remote ages facilitated this variety of fraud. Had the names of the coins been changed when the quantity of metal contained in them was reduced, there would have been no room for misapprehension. But, though the weight of the coins was undergoing perpetual, and their purity occasional, reductions, their ancient denominations were almost uniformly preserved. And those who saw coins of a certain weight and fineness circulate under the names of florins, livres, and pounds, and who saw them continue to circulate as such, after both their weight and their fineness had been lessened, began to think that they derived their value more from the stamp affixed to them by authority of government, than from the quantity of the precious metals which they contained. This was long a very prevalent opinion. But the rise of prices which invariably followed every reduction of the standard, and the disturbance which it occasioned in every pecuniary transaction, undeceived the public, and taught them, though it may not yet have taught their rulers, the expediency of preserving the standard of money inviolate.

Before proceeding to notice the changes made in the currency of this and other countries, it may be proper to observe that the standard is generally debased in one or other of the undermentioned ways.

How the
standard is
reduced.

First, by altering the denominations of the coins, without making any alteration in their weight or purity. Thus, suppose sixpence, or as much silver as there is in a sixpence, were called a shilling, then a shilling would be two shillings, and twenty of these shillings, or ten of our present shillings, would make a pound sterling. This would be a reduction of fifty per cent. in the standard.

Secondly, the standard may be reduced, by continuing to issue coins of the same weight, but making them baser, or with less pure metal and more alloy.

Thirdly, it may be reduced by making the coins of the same degree of purity, but of diminished weight, or with less pure metal; or it may be reduced partly by one of these methods, and partly by another.

The first of these methods of degrading the standard was recommended by Mr. Lowndes in 1695; and if injustice is to be done, it is, on the whole, the least mischievous mode in which it can be perpetrated. It saves all the trouble and expense of a recoinage; though, as it renders the fraud too obvious, it has been but seldom resorted to. But in inquiries of this kind, it is rarely necessary to investigate the manner in which the standard has been degraded. And by its reduction or degradation, is usually meant a diminution of the quantity of pure metal contained in coins of the same denomina-

tion without regard to the mode in which it may have been effected.

Money.

Conformably to what has been observed in the first section of this treatise, relative to the universality of the ancient practice of weighing the precious metals in every exchange, it is found that the earliest coins of most countries had the same names and were of the same ponderosity as the weights commonly used in them. Thus, the *talent* was a weight used in the earliest periods by the Greeks, the *as* or *libra* by the Romans, the *livre* by the French, and the *pound* by the English, Scotch, &c.; and the coins originally in use in Greece, Italy, France, and England, received the same denominations, and weighed a talent, a libra or pondo, a livre, and a pound. The standard has not, however, been preserved inviolate, either in ancient or modern times. But to attempt to trace these changes with any degree of minuteness, would lead us into too many details; and we shall content ourselves with referring to those only which seem to be of most importance.¹

Roman Money.—We learn from Pliny, that the first Roman coinage took place in the reign of Servius Tullius; that is, according to the common chronology, about 550 years before Christ. The *as*, or *libra*, of this early period, contained a Roman pound of copper, the metal then exclusively used in the Roman coinage, and was divided into twelve parts or *uncia*. If we may rely on Pliny, this simple and natural system was maintained until 250 years before our æra, or until the first Punic war, when the revenues of the state being insufficient, it was attempted to supply the deficiency, by reducing the weight of the *as* from twelve to two ounces. But it is extremely improbable that a government, which had maintained its standard inviolate for 300 years, should have commenced the work of degradation, by at once reducing it to a *sixth part* of its former amount; and it is equally improbable that so sudden and excessive a reduction should have been made in the value of the current money of the state, and, consequently, in the debts of individuals, without occasioning the most violent commotions. Nothing, however, is said in any ancient writer to entitle us to infer that such really took place; and we, therefore, concur with those who think that the weight of the *as* had been previously reduced, and that its diminution, which, it is most probable, would be gradual and progressive, had merely been carried to the extent mentioned by Pliny during the first Punic war. In the second Punic war, or 215 years B. C., a further degradation took place, and the weight of the *as* was reduced from two ounces to one ounce. And by the Papyrian law, supposed to have passed when Papyrius Turdus was tribune of the people, 175 years B. C., the weight of the *as* was reduced to half an ounce, or to 1-24th part of its ancient weight, at which it continued till Pliny's time, and long afterwards.²

The denarius, the principal silver coin in use amongst the Romans for a period of 600 years, was coined five years before the first Punic war, and was, as its name

² "Servius rex primus signavit æs. Antea rudi usos Romæ Remus tradit. Signatum est nota pecudum unde et pecunia appellata. . . . Argentum signatum est anno urbis DLXXXV. Q. Fabio Cos. quinque annos ante primum bellum Punicum. Et placuit denarius prox. libris æris, quinarius pro quinque, sesterterium pro dipondio ac semisse. Libræ autem pondus æris imminutum bello Punico primo cum impensis resp. non sufficeret, constitutumque ut asses sextentario pondere ferirentur. Ita quinque partes factæ luci, dissolutumque æs alienum. . . . Postea, Annibale urgente, Q. Fabio Maximo Dictatore, asses unciales facti: placuitque denarium xvi. assibus permutari, quinarium octonis, sesterterium quaternis. Ita resp. dimidium lucrata est. Mox lege Papyria semunciales asses facti." Plin., *Hist. Nat.*, lib. xxxij. cap. 3. Lugd. Bat. 1669

Money. imports, rated in the mint valuation at ten asses. Mr Greaves, whose dissertation has been deservedly eulogised by Gibbon,¹ shows that the denarius weighed at first only *one-seventh* part of a Roman ounce,² which, if Pliny's account of the period when the weight of the as was first reduced be correct, would give the value of silver to copper in the Roman mint as 840 to 1, which Greaves very truly calls a "most unadvised proportion." But if we suppose with Pinkerton,³ that, when the denarius was first issued, the as only weighed three ounces, the proportion of silver to copper would be as 252 to 1—a proportion which, when the as was soon afterwards reduced to two ounces, would be as 168 to 1, or about a third more than in the British mint. When, in the second Punic war, the as was reduced from two ounces to one, the denarius was rated at sixteen asses.

During his stay in Italy, Greaves weighed many consular denarii; that is, as he explains himself, denarii which were struck after the second Punic war and previously to the government of the Cæsars; and he found, by frequent and exact trials, that the best and most perfect of them weighed 62 grains English troy weight.⁴ Now, as the English shilling (new coinage) contains very nearly 87½ grains standard silver, this would give 8½d. for the value of the consular denarius. We should, however, fall into the greatest mistakes, if we indiscriminately converted the sums mentioned in the Latin authors by this or any other fixed proportion. It is not enough to determine the real value of a coin, to know its weight: the degree of its purity, or the fineness of the metal of which it is made, must also be known. But Greaves assayed none of the denarii which he weighed. And though it were true, as most probably it is, that, from the first coinage of silver in the 485th year of the city to the reign of Augustus, the weight of the denarius remained constant at ¼th part of a Roman ounce, or about 62 grains; and that, from the reign of Augustus to that of Vespasian, it only declined in weight from ¼th to ⅓th of an ounce;⁵ still it is abundantly certain that its real value was reduced to a much greater extent. The authority of Pliny, in this respect, is decisive; for he states that Livius Drusus, who was tribune of the people in the 662nd year of the city, or 177 years after the first coinage of silver, debased its purity, by alloying it with ⅓th part of copper.⁶ And, in a subsequent chapter (the ninth) of the same book, he informs us that Antony the triumvir mixed iron with the silver of the denarius; and that, to counteract these abuses, a law was afterwards made, providing for the assay of the denarii. Some idea of the extent to which the purity of the coins had been

debased, and of the disorder which had in consequence been occasioned, may be formed from the circumstance, also mentioned by Pliny, of statues being everywhere erected in honour of Marius Gratidianus, by whom the law for the assay had been proposed. But this law was not long respected; and many imperial denarii are now in existence, consisting of mere plated copper.⁷

Gold was first coined at Rome sixty-two years after Aureus, silver, in the 547th year of the city, and 204 years B.C. value of. The aureus originally weighed ⅙th part of the *pondo*, or Roman pound; but, by successive reductions, its weight was reduced, in the reign of Constantine, to only ⅓th part of a pound. The purity, however, as well as the weight of the aureus, was diminished. Under Alexander Severus it was alloyed with ⅓th part of silver. We learn from Dion Cassius, a contemporary of Severus, that the aureus was rated at twenty-five denarii, a proportion which Pinkerton thinks was always maintained under the emperors.⁸

The want of attention to this progressive degradation, Sestertius, has led the translators of ancient writers and their com- value of. mentators to the most erroneous conclusions. The sestertius, or money unit of the Romans, was precisely the fourth part of a denarius.⁹ When, therefore, the latter was worth 8½d., the former must have been worth 2½d. But the sestertius being thus plainly a multiple of, and bearing a fixed and determined proportion to the denarius, and consequently to the as, the aureus, and the other coins generally in use, it would partake of their fluctuations. When they were reduced, it would be likewise reduced; for had it not, or had the number of degraded denarii and aurei contained in a given sum of sestertii been increased in proportion to their degradation, nothing, it is obvious, would have been gained by falsifying the standard. Inasmuch, however, as we know that on one occasion the republic got rid of half of its debts, *dimidium lucrata est*, by simply reducing the standard of the as, the value of the sestertius must have fallen in the same proportion, just as in England we should reduce the pound sterling by reducing the shillings of which it is made up.¹⁰

Arbuthnot's "Tables of Ancient Coins," which, for a Errors of Arbuthnot and others, lengthened period, were considered of high authority, are constructed on the hypothesis that the consular denarii weighed by Greaves were of the same purity as English standard silver, and that no subsequent diminution was made either in their weight or fineness. The conclusions derived from such data, though differing in degree, are of the same character as those which we should arrive at, if, in estimating the value of the pound sterling during

¹ *Decline and Fall*, vol. iii. p. 89.

¹⁰ Writers on ancient coins, with the exception of Pinkerton, agree in supposing the sestertius to have been originally, and to have always continued to be, a silver coin. Pinkerton, however, has denied this opinion; and, on the authority of the following passage of Pliny, contends that the sestertius was, at the time when Pliny wrote, whatever it might have been before, a brass coin. "Summa gloria æris nunc in Marianum conversa, quod et Cordubense dicitur. Hoc a Liviano cadmiam maxime sorbet, et orichalci bonitatem imitatur in SESTERTIIS, DUPONDARIISQUE, Cyprio suo ASSIBUS contentis."—(Lib. xxxiv. cap. 2). That is, literally, "The greatest glory of brass is now due to the Marian, also called that of Cordova. This, after the Livian, absorbs the greatest quantity of *lapis calaminarius*, and imitates the goodness of orichalcum (*yellow brass*) in our SESTERTII and DUPONDARI, the asses being contented with the Cyprian (brass)." [Pliny had previously observed that the Cyprian was the least valuable brass.] This passage is, we think, decisive in favour of Pinkerton's hypothesis. But, in the absence of positive testimony, the small value of the sestertius might be relied on as a pretty sufficient proof that it could not be silver. When the denarius weighed 62 grains, the sestertius must have weighed 15½, and been worth 2½d.; but a coin of so small a size as to be scarcely equal to *one-third* part of one of our sixpences, would have been extremely apt to be lost, and could not have been struck by the rude methods used in the Roman mint with anything approaching to even tolerable precision. It is, therefore, more reasonable to suppose that it was of brass.

Money. the last hundred years, we took for granted that it contained a pound weight of standard silver, as in the period from the Conquest to the reign of Edward I. And, in addition to this source of error, the sums in ancient writers were, probably, at first set down with little regard to accuracy; and they have been peculiarly obnoxious to error from the carelessness of copyists and transcribers. But, however explained, many of the statements in the classics, as rendered by Arbuthnot and others, are quite incredible. Thus, we are told that Julius Cæsar, when he set out for Spain, after his prætorship, was £2,018,229 sterling worse than nothing; that Augustus received, in legacies from his friends, £32,291,666; that the estate of Pallas, a freedman of Crassus, was worth £2,421,875, and, which is still better, that he received £121,093 as a reward for his virtues and frugality; that Æsop, the tragedian, had a dish served up at his table which cost £4848; that Vitellius spent £7,265,625 in twelve months, in eating and drinking; and that Vespasian, at his accession to the empire, declared that an annual revenue of £322,916,666 would be necessary to keep the state machine in motion. It is astonishing that but few of our scholars or commentators seem to have been struck with the palpable extravagance of these and similar statements; though, to use the words of Garnier, they have brought "l'Histoire Ancienne, sous le rapport des valeurs, au même degré de vraisemblance que les contes de *Mille et un Nuits*." It should be remembered that, from the greater poverty of the mines of the old world, and the comparatively small progress made in the art of mining, the value of gold and silver was much—probably four times—greater in antiquity than at present. But, without taking this circumstance into account, the computations referred to are too obviously absurd to deserve any attention. Vespasian would have been very well satisfied with a revenue of twenty millions; and there are good grounds for supposing that the Roman revenue, when at the highest, never amounted to so large a sum.¹

Notice of
French
money.

French Money.—From about the year 800, in the reign of Charlemagne, to the year 1103, in that of Philip I., the French *livre*, or money unit, contained exactly a pound weight or twelve ounces (poids de marc) of pure silver. It was divided into twenty sols, each, of course, weighing one-twentieth part of a pound. This ancient standard was first violated by Philip I., who diminished considerably the quantity of pure silver contained in the sols. The example, once set, was so well followed up, that in 1180 the *livre* was reduced to less than a *fourth* part of its original weight of pure silver. In almost every succeeding reign there was a fresh diminution. "La monnoye," says Le Blanc, "qui est la plus précieuse et la plus importante de mesures, a changé en France presque aussi souvent que nos habits ont changé de mode." And to such an extent had the process of degradation been carried, that, at the Revolution, the *livre* did not contain a *seventy-eighth* part of the silver contained in the *livre* of Charlemagne. It would then have required 7885 *livres* really to extinguish a debt of 100 *livres* contracted in the ninth or tenth centuries; and an individual who, in that remote period, had an annual income of 1000 *livres*, was as rich, in respect to money, as those who, at the Revolution, enjoyed a revenue of 78,850 *livres*.²

Degradation
of the
livre.

We subjoin an abridged table calculated by M. Denis, exhibiting the average value of the French *livre* in

different periods, from the year 800 to the Revolution.—Money.

Those who wish for a detailed account of the various changes in the weight and purity of French coins, may, besides the excellent work of Le Blanc, consult the elaborate and very complete tables at page 905 of the "Traité des Mesures" of (Pauca), and at page 197 of the "Essai sur les Monnoies" of Dupré de St. Maur.

It was not to be expected that degradations originating in the necessities, the ignorance, and the rapacity of a long series of arbitrary princes, should be made according to any fixed principle. They were sometimes the result of an increase in the denomination of the coins, but more frequently of a diminution of the purity of the metal of which they were struck. A degradation of this kind was not so easily detected; and, to render its discovery still more difficult, Philip of Valois, John, and some other kings, obliged the officers of the mint to swear to conceal the fraud, and to endeavour to make the merchants believe that the coins were of full value!³ Sometimes one species of money was reduced without any alteration being made in the others. No sooner, however, had the people, in their dealings, manifested a preference, as they uniformly did, for the money which had not been reduced, than its circulation was forbidden, or its value brought down to the same level with the rest.⁴ To render the subject more obscure, and the better to conceal their incessant frauds, individuals were at one time compelled to reckon exclusively by *livres* and *sols*, at other times by crowns or *écus*; and not unfrequently they were obliged to refer, in computing, to coins which were neither *livres*, *sols*, nor crowns, but some multiple or fractional part thereof. The injurious effects of these constant fluctuations in the value of money are forcibly depicted by the French historians; and so insupportable did they become, that in the fourteenth and fifteenth centuries, several cities and provinces were glad to purchase the precarious and little respected privilege of

Money. having coins of a fixed standard, by submitting to the imposition of heavy taxes.¹

In Normandy, when it was governed by the English monarchs, there was a tax upon hearths, paid every three years, called *monetagium*, in return for which the sovereign engaged *not to debase his coins*. This tax was introduced into England by our early kings of the Norman race; but Henry I., in the first year of his reign, was induced to abandon it, and it has not since been revived.²

According to the present regulations of the French mint, the coins contain $\frac{9}{10}$ ths pure metal, and 1-10th alloy. The *franc*, which is equal to 1 livre 0 sols 3 deniers, weighs exactly 5 grammes, or 77·2205 English Troy grains. The gold piece of 20 francs weighs 102·96 English grains.³

English money, degradation of.

English Money.—In England at the epoch of the Norman conquest, the silver, or money pound, weighed exactly twelve ounces *Tower* weight (11 oz. 5 dwt. Troy.) It was divided into twenty shillings, and each shilling into twelve pence, or sterlings. This system of coinage, which is in every respect the same with that established in France by Charlemagne, had been introduced into England previously to the invasion of William the Conqueror, and was continued, without any alteration, till the year 1300, in the 28th Edward I., when it was for the first time violated, and the value of the pound sterling degraded to the extent of $\frac{1}{4}$ per cent. But the really pernicious effect of this degradation did not consist so much in the trifling extent to which it was carried by Edward, as in the example which it afforded to his less scrupulous successors, by whom the standard was gradually debased, until, in 1601, in the reign of Queen Elizabeth, 58s. instead of 20s. were coined out of the *Tower* pound weight of silver.

It may, perhaps, be right to mention, that in the 18th of Henry VIII. (1527), the pound Troy was substituted in mint valuations for the *Tower* pound, and has continued to be used in them down to the present time. This circumstance must always be kept in view in estimating the extent to which the standard has been degraded. When, for example, all tampering with it finally ceased in 1601, 62s. were coined out of a pound Troy. Hence, if we suppose, as is very often done, that the same pound had been used at the mint from the Conquest, it would follow that the degradation since the 28th Edward I. had been in the ratio of 20 to 62, or of 1 to 3 $\frac{1}{3}$ ths; whereas, in point of fact, it had really been in the ratio of 20 to 58, or of 1 to 2 $\frac{3}{5}$ ths.⁴ Practically, it may be said that the standard of money was reduced *two-thirds* between 1300 (28th Edward I.) and 1601, and hence, it is obvious that the stipulations in all contracts, entered into in the reigns immediately subsequent to the Conquest, might, in 1601, and since, be legally discharged by the payment of about a *third part* of the sums really bargained for. And yet the standard has been less degraded in England than in any other country.

The tables annexed to this article give an ample account of these degradations, and also give the weight of the gold coins, and the proportional value of gold to silver, estimated both by the mint regulations, and by the quantity of fine gold and fine silver contained in the different coins.

Scotch Money.—The English derived their system of coinage from the French, and the Scotch theirs from the English. From 1296 to 1355, the coins of both divisions of the island were of the same weight and purity. But at the last mentioned period, it was attempted to fill up the void in the currency of Scotland, occasioned by the remittance of the ransom of David II. to England, by degrading the coins. Down to this period, the money of the two kingdoms had been current in both on the same footing; and the preservation of this equality is assigned by Edward III. as a reason for his degrading the English coin. The English princes did not, however, keep pace with the Scotch in the career of degradation. Such was the mischievous energy of the latter, that in 1390 Scotch coin passed only for half its nominal value in England; and, in 1393, it was ordered that its currency as money in the latter should cease, and that its value should henceforth depend on the weight of the genuine metal contained in it. "To close this point at once," says Pinkerton, "the Scottish money, equal in value to the English till 1355, sunk by degrees, reign after reign, owing to succeeding public calamities, and the consequent impoverishment of the kingdom, till, in 1600, it was only a *twelfth* part of the value of English money of the same denomination, and remained at that point till the union of the kingdoms cancelled the Scottish coinage."⁵

Money. Scotch money, degradation of.

The annexed tables exhibit the successive degradations of the Scotch silver and gold coins.

At the Union, in 1707, it was ordered that all the silver coins current in Scotland, foreign as well as domestic, except English coins of full weight, should be brought to the Bank of Scotland, to be taken to the mint to be recoinced. In compliance with this order, there were brought in:—

Of foreign silver money (sterling), . . .	£132,080	17	9
Milled Scottish coins	96,856	13	0
Coins struck by hammer	142,180	0	0
English milled coin	40,000	0	0
Total	£411,117	10	9

Ruddiman conjectures, apparently with considerable probability, that the value of the gold and silver coins not brought in amounted to about as much more. Much suspicion was entertained of the recoinage. And that large proportion of the people who were hostile to the Union, and did not believe in its permanence, brought very little money to the Bank. A few only of the hoarded coins have been preserved, the far greater part having either been melted by the goldsmiths, or exported to other countries.⁶

Irish Money.—The gold and silver coins of Ireland are identical with those of Great Britain. The rate, however, at which they used to circulate in the former, or their nominal value as money of account, was 8 $\frac{1}{2}$ per cent. higher than in the latter. This difference of valuation, though attended with considerable inconvenience, subsisted from 1689 till 1825, when it was put an end to. For an account of the various species of metallic money which have at different times been current in Ireland, we beg to refer our readers to Simon's "Essay on Irish money."

¹ The President Henault says, speaking of the reign of John, the successor of Philip of Valois (1350-1364)—"La variation des monnoies sous ce prince, est la preuve la plus forte des malheurs de son regne; variation si subite que a grand peine estoit homme, qui en juste payement des monnoyes, de jour en jour se put connoître (*Rec. Des Ord.*) c'estoit le genre d'impôt de ce tems la, et sans doute le plus fatal au commerce; aussi le peuple obtint-il, comme une grace que il fut remplacé par les tailles et les aides."—*Ab. Money. Coins;”¹ a work pronounced by Ruding to be “the most valuable of all the publications on the coinage of any part of the united empire.”²

Money of Germany, &c. *Money of Germany, Spain, etc.*—“In many parts of Germany, the florin, which is still the integer or money of account of those countries, was originally a *gold* coin, of the value of about 10s. of our present money (old coinage). It is now become a silver coin, of the value of only 20d.; and its present value, therefore, is only equal to a sixth part of what it was formerly. In Spain, the maravedi, which was in its origin a Moorish coin, and is still the money of account of that kingdom, was in ancient times most frequently made of gold. Le Blanc observes, that in 1220 the maravedi weighed 84 grains of gold, equal in value to about 14s. (old coinage) of our present money. But this maravedi, though its value is not quite the same in all the provinces of Spain, is now become a small copper coin, equal in general to only 43-272 of an English penny! In Portugal, the re, or reis, is become of no greater value than 27-401ths of an English penny; it is so small, that in estimating its value in other coins, it is reckoned by hundreds and thousands. The moeda, or moidore, is equal to 4800 reis; and this little coin has now, in fact, no existence but in name. Such has been the fate of all these coins, and such is the present state of their depreciation.”³

Raising the value of coins in Rome; The principle of degradation has not, however, been uniformly acted upon. The bullion contained in coins of the same denomination, has sometimes, though rarely, been increased, and creditors enriched at the expense of their debtors. This method of swindling is said to have been first practised in the worst times of the Roman empire. The citizens being bound to pay into the imperial treasury a certain number of pieces of gold, or *aurei*, Heliogabalus, whose cunning appears to have been nowise inferior to his proverbial profligacy, increased the weight of gold in the *aureus*; and thus obtained, by an underhand trick, an addition to his means of dissipation, which he might not have been able to obtain by a fair and open proceeding.⁴ In France, the value of the coins has been frequently raised. During the early part of the reign of Phillip le Bel, who ascended the throne in 1285, the value of the coin had been reduced to such an extent as to occasion the most violent complaints on the part of the clergy and landholders, and generally of all that portion of the public whose incomes were not increased proportionally to the reduction in the value of money. To appease this discontent, and in compliance with an injunction of the pope, the king consented to issue new coins of the same denomination with those previously current, but which contained about *three* times the quantity of silver. This, however, was merely shifting an oppressive burden from the shoulders of one class to those of another less able to bear it. The degraded money having been in circulation for about sixteen years, by far the largest proportion of the existing contracts must have been adjusted with reference to it. No wonder, therefore, that debtors should have felt indignant at the injustice done them by this enhance-

ment of the value of money, and that they refused to make good their engagements otherwise than in money of the value of that which had been current when they were entered into. The labouring class, to whom every change in the value of money is injurious, having joined the debtors in their opposition, they broke out into open rebellion. “The people,” says Le Blanc, “being reduced to despair, and having no longer anything to care for, lost the respect due to the edict of his majesty; they pillaged the house of the master of the mint, who was believed to have been the chief adviser of the measure, besieged the Temple, in which the king lodged, and did all that an infuriated populace is capable of doing.”⁵ The sedition was ultimately suppressed. It is not mentioned whether any abatement were made, by authority, from the claims of the creditors, in the contracts entered into when the light money was in circulation. It seems probable, however, from what is elsewhere mentioned by Le Blanc,⁶ that such was really the case.

The history of the French coinage affords several instances similar to that now brought under the notice of the reader. But, in England, the new coinage in the last year of Edward VI. is the only instance in which the value of money has been augmented by the direct interference of government. Previously to the accession of Henry VIII., the pound of standard silver bullion, containing 11 oz. 2 dwts. of pure silver, and 13 dwts. of alloy, was coined into thirty-seven shillings and sixpence. Henry, however, not only increased the number of shillings coined out of a pound weight of silver, but also debased its purity. The degradation was increased under his son and successor, Edward VI., in the fifth year of whose reign seventy-two shillings were coined out of a pound weight of bullion; and as this bullion contained only *three* ounces of pure silver to *nine* ounces alloy, twenty of these shillings were only equal to 4s. 7½d of our present money, including the seignorage.⁷ It appears from the proclamations issued at the time, and from other authentic documents, that this excessive reduction of the value of silver money occasioned the greatest confusion. A *maximum* was set on the prices of corn and other necessities, and letters were sent to the gentlemen of the different counties, desiring them to punish those who refused to carry their grain to market. But it was soon found to be quite impossible to remedy these disorders otherwise than by withdrawing the base money from circulation. This was accordingly resolved upon; and in 1552 new coins were issued of the old standard in respect of purity; and which, though less valuable than those in circulation during the early part of the reign of Henry VIII., were above *four* times the value of a large proportion of the coins of the same denomination that had been in circulation for some years before.

It is, however, all but certain that such a rise in the value of money could not have taken place without occasioning the most violent commotions, had *all* the coins previously in circulation been debased. Equal injustice, it must be remembered, is always done to the poorest and not least numerous class of society, by increasing the value of money, that is done to the wealthier classes by its depression. And, though government had

¹ Originally printed at Dublin in 1749, in 4to, and reprinted with some additions in 1810.

Money.

been disposed to sanction so enormous an invasion of the right of property, it is altogether impossible that the country could have submitted to have had 400 or 450 per cent. added to its taxes and other public burdens by a legerdemain trick of this kind, or that individuals would have consented to pay so much more than they had originally bargained for. Instead of deserving praise for accomplishing such a measure, Edward VI., who began the reformation of the coins, and Elizabeth, by whom it was completed, would have justly forfeited the esteem of their subjects, and lost their popularity. In truth, however, little or no change had been made during all this period in the value of the gold coins; and there is, besides, abundance of evidence to show that many of the old silver coins had remained in circulation. And as there is no mention made of the issue of the new coins having been attended with any inconvenience, it is nearly certain, as Mr Harris has remarked, that, during the period of the debasement of the standard, individuals had regulated their contracts chiefly with reference to the gold or old silver coins; or, which is the same thing, that "they had endeavoured, as well as they could, to keep by the standard, as it had been fixed in the preceeding times."¹

We have been thus particular in examining this measure, because it has been much referred to. It is plain, however, that it gives no support to the arguments of those who appeal to it as affording a striking proof of the benefits which they affirm must always result from restoring a debased or degraded currency to its original purity or weight. Invariability of value is the great desideratum in a currency. To elevate the standard, after it has been for a considerable period² depressed, is not a measure of justice, but of new injustice. It vitiates and falsifies the provisions in one set of contracts, that those in another set may be properly adjusted.

This, however, as already remarked, is the only instance in which the government of England has interfered directly to enhance the value of money. In every other case, where they have tampered with the standard, it has been to lower its value, or, which comes to the same thing to reduce their own debts and those of their subjects.

Pernicious effects of changes of the standard.

It is unnecessary to enumerate in detail the various bad consequences of these successive changes in the standard of value. But it deserves to be remarked, that its reduction does not afford any real relief to the governments by whom so miserable a fraud is perpetrated. Their debts are, it is true, reduced, but so are their revenues. A coin that has been degraded will not exchange for, or buy, the same quantity of commodities that it previously did. If the degradation be 10 per cent., government, and every one else, will very soon be compelled to pay £110 for commodities or services which were previously obtainable for £100. Hence, to bring the same real value into the coffers of the treasury, it is necessary that taxation should be increased whenever the standard is diminished; a measure always odious, and sometimes impracticable.

A corresponding reduction of revenue is not, however, the only bad effect resulting to such governments as are dishonest enough to reduce the standard of money. They must not expect to borrow on the same favourable terms as those who act with good faith. The lenders of money to knaves always stipulate for a proportionally high rate of

interest. They not only bargain for as much as may be got from secure investments, but also for an additional rate, or premium, to cover the risk of dealing with those who have given proofs of bad faith, and on whose promises no reliance can be placed. A degradation of the standard is, therefore, about the most wretched device to which a bankrupt government can have recourse. It will never, indeed, be resorted to except by those who are as ignorant as they are unprincipled. "It occasions," says Dr. Smith, "a general and most pernicious subversion of the fortunes of private people; enriching, in most cases, the idle and profuse debtor at the expense of the frugal and industrious creditor, and transporting a great part of the national capital from the hands which were likely to increase and improve it, to those who are likely to dissipate and destroy it. When it becomes necessary for a state to declare itself bankrupt, in the same manner as when it becomes necessary for an individual to do so, a fair, open, and avowed bankruptcy is always the measure which is both least dishonourable to the debtor and least hurtful to the creditor. The honour of a state is surely very poorly provided for, when, in order to cover the disgrace of a real bankruptcy, it has recourse to a juggling trick of this kind, so easily seen through, and at the same time so extremely pernicious."

Some of the bad consequences resulting from changes in the value of money might be obviated, by enacting that the stipulations in preceding contracts should be made good, not according to the present value of money, but according to its value at the time when they were entered into. This principle, which is conformable to the just maxim of the civil law (*Valor monetæ considerandus atque inspiciendus est, a tempore contractus, non autem a tempore solutionis*), was acted upon, to a certain extent, at least, by the kings of France during the middle ages. Ordinances of Philip le Bel, Philip of Valois, and Charles VI., issued subsequently to their having increased the value of money, or, as the French historians term it, returned from the "*foible*" to the "*forte monnaie*," are still extant, in which it is ordered that all preceding debts and contracts should be settled by reference to the previous standard. But, though the same reason existed, it does not appear that any such ordinances were ever issued when the value of money was degraded. It is obvious, indeed, that a government would derive no advantage from reducing the value of money, were it to order, as it is in justice bound to do, that all preceding contracts should be adjusted by the old standard. Such a measure would reduce the revenue without reducing the national incumbrances; while, by establishing a new standard of value, and unsettling the notions of the public, it would open a door for many abuses, and be productive of infinite confusion and disorder in the dealings of individuals.

The odium, and positive disadvantage attending the degradation of metallic money, have at length induced most governments to abstain from it. But they have only renounced one mode of playing at fast and loose with the property of their subjects, to adopt another and a still more pernicious one. The injustice which was formerly done by diminishing the bullion contained in coins, is now perpetrated with greater ease, and to a still more ruinous extent, by the depreciation of paper currency.

¹ Harris *On Coins*, part ii. p. 3.

² It is of course impossible to define such periods, in as much as that depends on the peculiar circumstances affecting the country at the time. Probably, however, were the standard reduced for some ten or twelve years, as great injustice would be done by raising it to its old level as by continuing to use it as reduced, or perhaps greater.

¹ 1527, Henry VIII.] The Saxon or Tower-pound was used at the mint up to this time, when the pound troy was substituted in its stead. The Tower-pound was but 11 oz. 5 dwts. troy; so that, from the Conquest to the 28th of Edward I., twenty shillings in tale were exactly a pound in weight.

² 1666, 18 Charles II.] The seignorage on the coinage was at this time given up, and the gold bullion brought to the mint has ever since been coined free of expence. A seignorage of 6¼ per cent. was imposed on the coinage of silver by 56th Geo. III.

No. II.

ENGLISH MONEY.—Account of the quantity of fine silver coined into 20s. or the pound sterling; the quantity of standard silver, of 11 oz. 2 dwts. fine, and 18 dwts. alloy, contained in 20s. or the pound sterling, and the quantity of standard silver which was delivered to the mint, by the public, for 20s. of silver money, in the different reigns, from the time of Edward I. to the reign of George III. A similar account with respect to gold. And an account of the proportionate value of fine gold to fine silver, according to the number of grains contained in the coins; and the proportionate value of fine gold to fine silver, according to the price paid by the mint to the public. Calculated in grains and 1000 parts troy-weight.

¹ 1551, 5 Edward VI.] The coinage of debased silver money in the 5th year of Edward VI. of 9 oz. fine, ought more properly to be considered as tokens. The sum of £120,000 only was so coined. (See James's *Essays*, chap. iv.)

² 1816, 56 George III.] The government having taken the coinage of silver into its own hands, there is at present no fixed price paid to the public, by the mint for standard silver. And supposing the government to continue the present mint regulations, and to keep gold at 77s. 10½d. an ounce, as the price of silver varies, the relative value of gold to silver will vary in like proportion.

Tables. No. III.—SCOTS MONEY.—*Account of the Number of Pounds, Shillings, and Pennies Scots, which have been coined out of One Pound Weight of Silver, at different times; with the degree of Purity of such Silver, or its Fineness, from the year 1107 to the year 1601. Tables.

Tables.

No. VI. Table specifying the Value of the Monies of Account of the principal Places with which this Country has Exchange Transactions, taking Silver at 5s. an oz., and specifying also the *Par* of Exchange with such Places on this Hypothesis.—(Abstracted from *Tate's Modern Cambist*, to which the reader is referred for further explanations.)

				Par of Exchange.			
Petersburg -	100 copecks	= 1 rouble	= 3s. 1½d.	giving	6 roub. 40 cop.	= 1l.	
Berlin -	30 sil. groschen	= 1 Pruss. doll.	= 2s. 10¾d.	—	6 doll. 27 s. g.	= 1l.	
Copenhagen -	96 skillings	= 1 Rig. doll.	= 2s. 2¾d.	—	9 doll. 10 sk.	= 1l.	
Hamburg -	16 schillings	= 1 mark	= 1s. 5¾d.	—	13 mks. 10½ sch.	= 1l.	
Amsterdam -	100 centimes	= 1 florin	= 1s. 8d.	—	11 fl. 97 cents	= 1l.	
Antwerp -	100 centimes	= 1 florin	= 1s. 8d.	—	11 fl. 97 cents	= 1l.	
Paris -	100 centimes	= 1 franc	= 9¼d.	—	25 fr. 57 cents	= 1l.	
Frankfort -	24½ guld. or flor.	= 1 mark	= 1s. 7¾d.	—	12½ guldens	= 1l.	
Vienna -	60 kreusers	= 1 florin	= 2s. 0¾d.	—	9 fl. 50 kr.	= 1l.	
Venice -	100 centesimi	= 1 lira Austriaca	= 8½d.	—	29 li. 52 cent.	= 1l.	
Genoa -	100 centesimi	= 1 lira Nuova	= 9¼d.	—	25 li. 57 cent.	= 1l.	
Leghorn -	100 centesimi	= 1 lira Toscana	= 7½d.	—	30 li. 69 cent.	= 1l.	
Madrid -	8 reals	= 1 dollar of Plate	= 3s. 1½d.	—	6 doll. 2½ reals	= 1l.	
Lisbon -	1000 reis	= 1 milreis	= 4s. 8d.	—	4 mil. 285 reis	= 1l.	
New York -	100 cents	= 1 dollar	= 4s. 2d.	—	4 doll. 80 cents	= 1l.	
Rio Janeiro -	1000 reis	= 1 milreis	= 2s. 7d.	—	7 mil. 777 reis	= 1l.	
Havannah -	100 cents	= 1 dollar	= 4s. 6¾d.	—	4 doll. 44 cents.	= 1l.	

It is easy from this table to calculate the value of any of the above coins, taking silver at 5s. 2d., 5s. 6d. an oz., or at any other price, and thence to deduce the par of exchange at such rates. The values of the coins in the Table of Coins are estimated on the hypothesis that silver is worth 5s. 2d. an ounce.

No. VII. GOLD COINS OF DIFFERENT COUNTRIES.—A Table containing the Assays, Weights, and Values of the principal Gold Coins of all Countries, computed according to the Mint Price of Gold in England, and from Assays made both at London and Paris, which have been found to verify each other.¹

COINS.				Assay.	Weight.	Standard Weight.	Contents in Pure Gold.	Value in Sterling.
				Car. gr.	Dwt. gr.	Dwt. gr. m.	Grains.	s. d.
AUSTRIAN DOMINIONS, Souverain -				W. 0 0½	3 14	3 13 15	78·6	13 10·92
Double Ducat -				B. 1 2½	4 12	4 20 5	106·4	18 9·97
Ducat Krennütz, or Hungarian -				B. 1 3	2 5¾	2 10 3	53·3	9 5·91

Ducat -				B. 1 0½	2 5¾	2 8 9	51·8	9 2·
DENMARK - Ducat current -				W. 0 3¾	2 0	1 21 19	42·2	7 5·62
Ducat specie -				B. 1 2	2 5¾	2 9 8	52·6	9 3·70
Christian d'or -				W. 0 1	4 7	4 5 16	93·3	16 6·14
ENGLAND - Guinea -				Stand.	5 9½	5 9 10	118·7	21 0·
Half-guinea -				Stand.	2 16¾	2 16 15	59·3	10 6·
Seven shilling piece -				Stand.	1 19	1 19 0	39·6	7 0·
Sovereign -				Stand.	5 3¼	5 3 5	113·1	20 0·
FRANCE - Double Louis (coined before 1786) -				W. 0 2	10 11	10 5 6	224·9	39 9·64
Louis -				W. 0 2	5 5½	5 2 12	112·4	10 10·71
Double Louis (coined since 1786) -				W. 0 1½	9 20	9 15 19	212·6	37 7·53
Louis -				W. 0 1½	4 22	4 19 19	106·3	18 9·75
Double Napoleon, or piece of 40 francs -				W. 0 1¾	8 7	8 3 0	179·	31 8·36
Napoleon, or piece of 20 francs -				W. 0 1¾	4 3½	4 1 10	89·7	15 10·5
FRANKFORT ON THE MAINE, Ducat -				B. 1 2½	2 5¾	2 9 14	52·9	9 4·34
GENEVA - Pistole, old -				W. 0 2	4 7¼	4 4 18	92·5	16 4·45
Pistole, new -				W. 0 0½	3 15½	3 15 4	80·	14 1·9
GENOA - Sequin -				B. 1 3½	2 5¾	2 10 6	53·4	9 5·41
HAMBURGH - Ducat (double in proportion) -				B. 1 2½	2 5¾	2 9 14	52·9	9 4·35

¹ The London Assays in this Table were made by Robert Bingley, Esq., F.R.S., the King's Assay Master of the Mint, and those at Paris by Pierre Frédéric Bonneville, Essayer du Commerce, as published in his elaborate work on the coins of all nations.

Specimens of all the foreign coins brought to London for commercial purposes have been supplied for this Table from the Bullion-office, Bank of England, by order of the Bank Directors, and have been selected by John Humble, Esq., the chief clerk of that office, who also examined the Tables in their progress. It may likewise be added, that the Mint Reports of these commercial coins are chiefly from average assays; and that all the computations have been carefully verified by different calculators.—(Note by Dr. Kelly, to second edition of the *Cambist* published in 1821.)

¹ "By one of the articles of the Zollverein, or Customs-union of Germany, it was stipulated that the settlements for the duties should be made either in Prussian dollars or in florins, at the rate of seven florins for four Prussian dollars. There were, however, no florins in existence exactly of this value; but as the nearest approach to it was a valuation called the 24 guldenfuss, or florin-foot, these Zollverein florins were nominally reckoned to be in this rate, though the difference amounts to more than 2 per cent.

"The term 24 guldenfuss implies that the mark weight of fine silver is rated at 24 gulden or florins. It was formed by giving to the coins minted or valued in 20 guldenfuss an increased value of one-fifth, as rating the 20 kreutzer piece at 24 kreutzers. At 60d. per ounce standard, the value of this mark of fine silver is worth 40s. 7 $\frac{1}{2}$ d. sterling, from which the value of the different German monetary integers is readily obtained; as reckoning 27 $\frac{1}{2}$ marks banco or 34 marks current of Hamburg, 14 dollars of Prussia, 24 $\frac{1}{2}$ florins of South Germany, 20 florins of Austria, and also 60 lire Austriache of Lombardy, to be of this amount.

"In order, therefore, to prevent the loss or inconvenience which would attend their adhering to this mode of valuation, a money convention was entered into on the 25th of August 1837, among the states forming the union, by which it was agreed upon that a new basis of valuation should be adopted for their coins, under the term of Süddeutscher Währung, or South German valuation, at the rate of 24 $\frac{1}{2}$ gulden or florins from the mark's weight of fine silver.

"Bavaria, Wirtemberg, Baden, and Saxony have since issued their coins at this rate, and the other states of the confederation are doing or preparing to do the same. Among them Frankfort, in 1840, began the mintage of coins of this value; and by a regulation of the Chamber of Commerce of this free city, all the rates of exchange, as well as the values of bullion and foreign coins, were ordered to be expressed in this Süddeutscher Währung from the beginning of this present year (1843). One of these new and very exactly minted florins was assayed by Messrs. Johnson and Cook, of Hatton Garden, who reported it to be, full weight, 6 dwts. 19 $\frac{1}{2}$ grains, worse 6 dwts., gold under 2 grains; from which the value, at 60d. per ounce standard, is very exactly 19 $\frac{1}{2}$ d. sterling, making the par of exchange with London 120 $\frac{1}{2}$ florins in S. D. W. for £10 sterling.

"I have been thus particular in these explanations, partly because several persons imagine that the late alteration in the rate of exchange with Frankfort was made in compliance with the wishes, or to suit the convenience, of one or more of our leading houses in exchange negotiations, but more particularly because it is maintained by many that the valuation of this rate is not merely nominally, but really, in 24 guldenfuss. This is a point of no small importance to the commercial world, for had it been so, the par of exchange with London would have been only 118 florins for £10 sterling, and the difference between this and the present price of sight bills on Frankfort would have exceeded 2 $\frac{1}{2}$ per cent.; a variation which every practical cambist well knows could not exist, except under very extraordinary circumstances, and with nearly corresponding differences in the other rates of exchange: neither of which causes is now in operation."—(Letter of William Tate, Esq., cambist to the Times.)

Accounts used to be kept in Holland by the pound Flemish = 6 florins = 20 schillings = 120 stivers = 240 groats = 1920 pennings. But in 1820 the decimal system was introduced. In order, however, to cause as little inconvenience as possible, the florin = 1s. 8 $\frac{1}{2}$ d. sterling, was made the unit of the new system. The florin is supposed to be divided into 100 equal parts or cents; and the other silver coins are equal multiples or sub-multiples of it. The new gold coin is called the florin piece, and is worth 16s. 6 $\frac{1}{2}$ d. very nearly. But accounts are still sometimes kept in the old way, or by the pound Flemish. Par of exchange between Amsterdam and London is 11 flor. 58 cents per pound sterling.

N.B.—It was ordered by a ukase, dated the 1st of July 1839, that this coin should be the standard of value in Russia. It is divided into 100 copecks; and the other silver coins are of the value of 75, 50, 25, and 10 copecks each. This same ukase enacts, that 1 silver rouble shall henceforth be equal to 3 $\frac{1}{2}$ old paper roubles.										

¹ The Prussian coins, having been debased at different periods, vary in their reports.

	- Ditto, double	W. 0 3	1 18 $\frac{3}{4}$	1 18 2	39.	0 5.44
	- Gulden of the Dutch E. I. Co. (1820)	W. 0 7 $\frac{1}{2}$	6 22	6 16 6	148.4	1 8.72

The sterling value of the foreign coins in the foregoing tables has been computed from the assays as follows:—Let it be required to assign the value, in sterling, of a French double Louis d'or coined since 1786, the assay master's report being as follows: "Weight, 9 dwts. 20 grs.; assay W. 1 $\frac{1}{2}$ grs.," that is, 0 car. 1 $\frac{1}{2}$ grs. worse than the English standard. We proceed as under:—

From 22 car. 0 gr. the fineness of English standard gold, } There remains 21 car. 2 $\frac{1}{2}$ gr.
Take 0 car. 1 $\frac{1}{2}$ gr.

Then, as 22 car.: 21 car. 2 $\frac{1}{2}$ grs.: 9 dwts. 20 grs.: 9 dwts. 16 grs., the standard gold contained in the Louis d'or; and hence, as 1 oz.: £3, 17s. 10 $\frac{1}{2}$ d.: 9 dwts. 16 grs.: £1, 17s. 7 $\frac{1}{2}$ d., the value of the Louis in sterling money, and so for any of the other coins.

¹ This is the coin which is universally circulated under the name of the Spanish dollar.

PART II.—PAPER-MONEY.

SECT. I.—General Principles in regard to Paper-Money.

Paper-money.

We have endeavoured to explain, in the first part of this article, the reasons why paper has been substituted for coins in the ordinary transactions of society, and the principle on which its value is maintained. Besides being a source of profit to the issuers, the employment of paper, provided it be properly secured, is a great public accommodation. The weight of 1000 sovereigns exceeds twenty-one pounds troy, so that to pay or receive a large sum in metal would be exceedingly inconvenient; while a great risk from loss, as well as a heavy expense, would be incurred in the conveyance of specie from place to place. But with paper this may be effected with extreme facility, and payments of the largest sums, and at the greatest distances, may be made with almost no inconvenience or expense. And while the interest of individuals is thus consulted by the introduction and use of paper, it is of the greatest service to the public. Its employment, and the various devices for the economising of currency to which it has led, enable the business of a commercial country like England to be carried on with a *fourth part*, perhaps, of the gold and silver currency that would otherwise be necessary. The cheapest instruments by which exchanges can be effected are substituted for the dearest; and, besides doing their work better, this substitution enables the various sums which must otherwise have been in use as money, to be employed as capital in industrial undertakings. Of the various means, whether by the introduction of machinery or otherwise, that have been devised for promoting the progress of wealth and civilization, it would not be easy to point out one better calculated to attain its end than the introduction of a properly organised paper-money.

To prevent misconception, it may be necessary to premise that by "paper-money" we do not mean notes which are legal tender, though not payable in coin on demand. These, no doubt, are the only description of notes which can, strictly speaking, be called paper money. But as the circumstances which determine their value have been already stated, and as they happily have no existence amongst us, it is needless farther to allude to them. Hence, in the sequel of this article, when we employ the term paper-money, it will, unless the contrary be stated, apply exclusively to the notes issued by individuals or associations for certain sums, and made payable on demand, or on being presented. Though only the representatives of money, these notes possess so many of its qualities, and are so easily converted into coin, that they may, with little impropriety, be held to be money. Being most commonly issued by bankers, they are usually called bank-notes.

Distinction between bills of exchange and paper money.

This statement shows that, under the phrase paper-money or paper-currency, we do not include bills of exchange, or bills issued by bankers, merchants, and others, and payable sometime after date. Such bills perform, in some respects, the same functions as money; and have, in consequence, been frequently regarded in the same light as bank-notes. But this is quite improper; for though there are many points in which a bill of exchange and a bank-note closely resemble each other, there are others in which there is a distinct and material difference between them. A note bears to be payable on demand;

it is not indorsed by a holder on his paying it away; the party receiving has no claim on the party from whom he received it, in the event of the failure of the issuers;¹ and every one is thus encouraged, reckoning on the facility of passing it to another, to accept bank paper, "*even though he should doubt the ultimate solvency of the issuers.*"² Bills, on the contrary, are almost all drawn payable at some distant period; and those into whose hands they come, if they be not in want of money, prefer retaining them in their possession, in order to get the interest that accrues upon them. But the principal distinction between notes and bills is, that every individual in passing a bill to another, has to indorse it, and by doing so makes himself responsible for its payment. "A bill circulates," says Mr. Thornton, "in consequence chiefly of the confidence placed by each receiver of it in the last indorser, his own correspondent in trade; whereas the circulation of a bank-note is owing rather to the circumstance of the name of the issuer being so well known as to give it an universal credit."³ Nothing, then, can be more inaccurate than to represent bills and notes in the same point of view. If A pay to B £100 in satisfaction of a debt, there is an end of the transaction; but if A pay to B a bill of exchange for £100, the transaction is not completed; and, in the event of the bill not being paid by the person on whom it is drawn, B will have recourse upon A for its value. It is clear, therefore, that a great deal more consideration is always required, and may be fairly presumed to be given, before any one accepts a bill of exchange in payment, than before he accepts a bank-note. The note is payable on the instant, without deduction—the bill not until some future period; the note may be passed to another without incurring any risk or responsibility, whereas every fresh issuer of the bill makes himself responsible for its value. Notes form the currency of all classes, not only of those who are, but also of those who are not engaged in business, as women, children, labourers, &c. who in most instances are without the power to refuse them, and without the means of forming any correct conclusion as to the solvency of the issuers. Bills, on the other hand, pass only, with very few exceptions, among persons engaged in business, who are fully aware of the risk they run in taking them. There is plainly, therefore, a wide and obvious distinction between the two species of currency; and it cannot be fairly argued, that because government interferes to regulate the issue of the one, it should also regulate the issue of the other. To use the words of Lord Mansfield, "Bank-notes are not like bills of exchange, mere securities or documents for debts, nor are so esteemed, but are treated as money in the ordinary course and transactions of business, by the general consent of mankind; and on payment of them, whenever a receipt is required, the receipts are always given as for money, not as for securities or notes." (*Chitty on Bills*, 8th edition. p. 555.)

To obviate the endless inconveniences that would arise from the circulation of coins of every weight and degree of purity, were there no restrictions on their issue, all governments have forbidden the circulation of coins not of a certain specified or standard weight and fineness. And the recurrence of similar inconveniences from the

Regulations in regard to the issue of notes.

¹ Practically speaking, this is the fact; but a person paying away a bank note is liable to be called upon for repayment, should the bank fail before it was in the power of the party to whom it was paid, using ordinary diligence to present it. The responsibility seldom exceeds a couple of hours, and can hardly in any case exceed a couple of days. In practice it is never adverted to.

² Thornton on Paper Credit, p. 172.

³ Ibid, p. 40.

Money. issue of notes for varying sums, and payable under varying conditions, have led, in most countries in which paper-money is made use of, to the enacting of regulations forbidding the issue of notes below a certain amount, and laying down rules for their payment. In England at this moment no note payable to bearer on demand can be issued for less than five pounds, and they must all be paid the moment they are presented. In Scotland and Ireland the minimum value of bank-notes is fixed at one pound, the regulations as to payment being the same as in England. In order to preserve the monopoly of the London circulation to the Bank of England, no notes payable to bearer on demand are allowed to be issued by individuals or associations, other than the Bank of England, within sixty-five miles of St. Paul's. But beyond these limits they may be issued by certain banks, under the provisions of the Act 7 and 8 Vic. c. 32, &c.

Necessity of insuring the conversion of bank notes into coin.

The propriety of taking measures to insure the convertibility of bank-notes into coin has been previously explained. This is a matter which cannot safely be left to the discretion or judgment of individuals, but which must be settled by government. No bank-notes should be permitted to circulate, about the equivalency of which to the coins they profess to represent there can be the smallest room for doubt. It is alleged, indeed, that in this, as in most other things, we may safely trust to the prudence and sagacity of those who deal with banks; and that, if left to themselves, the public will very rarely be deceived. But the widest experience shows that but little, if any, dependence can be placed on this doctrine. The public is very apt to be misled, in the first instance, in giving confidence to or taking the paper of individuals or associations, and though that were not the case, the condition of an individual or company may change from bad or expensive management, improvident speculation, unavoidable losses, and fifty other things of which the public know nothing, or nothing certain. The fact that any particular banker who issues paper enjoys the public confidence, is, at best, a presumption merely, and no proof that he really deserves it. The public may believe him to be rich and discreet; but this is mere hypothesis; the circumstances which excite confidence at the outset, and which preserve it, are often very deceptive; and in the vast majority of instances the public has no certain knowledge, nor the means of obtaining any, as to the real state of the case. But it is unnecessary to argue this point speculatively. There have, unfortunately, been innumerable instances in which it has turned out that bankers who had long been in the highest credit, and whose notes had been unhesitatingly accepted by the public, have been found to be, on the occurrence of anything to excite suspicion, quite unable to meet their engagements.

The issue of notes is of all businesses that which seems to hold out the greatest prospect of success to the schemes of those who attempt to get rich by preying on the public. The cost of engraving and issuing is nothing compared with the sums for which they are issued: and provided they be got into any thing like extensive circulation, they become at once considerably productive. They are not issued, except, as previously explained, on the deposit of bills or other securities, yielding a considerable rate of interest; so that if an individual, or set of individuals, with little or no capital, should contrive by fair appearances, promises, and similar devices, to insinuate himself or themselves into the public confidence, and succeed in getting £20,000, £50,000, or £100,000 into circulation, he or they would secure a good income

in the meantime; and on the bubble bursting, and the imposture being detected, they would be no worse off than when they set up their bank. On the contrary, the presumption is, that they would be a great deal better off; and that they would take care to provide, at the cost of the credulous and deceived public, a reserve stock for their future maintenance. Hence, seeing that the facilities for committing fraud are so very great, the propriety or rather necessity of providing against them.

It is sometimes, no doubt, contended that the grand principle of the freedom of industry should be universally respected; that it can in no case be departed from with impunity; and that it is not only injurious but unjust to lay any restrictions upon the business of banking. But we are not to be led astray by a cuckoo-cry of this description. The business of banking—that is, of keeping and dealing in money—is one thing, while the manufacture and issue of notes intended to be substituted for and to serve as money, is another and a totally different thing. And though everybody may perhaps be allowed to undertake the former, it by no means follows that the same license is to be extended to those who make and issue notes. It is to be recollected that in matters of this sort, neither freedom nor restriction is, abstractly considered, just or unjust, good or bad, expedient or inexpedient. It is by their respective influence upon society that they are to be judged; and though a free and liberal course of policy be in general most for the public advantage, there are very many cases in which it is necessary to impose restrictions. It is admitted on all hands that governments are bound to suppress or regulate every business or pursuit which is likely otherwise to become publicly injurious. And does any one doubt that the issue of notes payable on demand is in the foremost class of these businesses? The experience of all ages and nations is conclusive as to this point. It has been everywhere regulated, in the most democratical as well as in the most despotic states, in England and Russia, Holland and France, the United States and Austria. The reasonableness of the practice accords with its uniformity.—*Le droit d'émettre des billets est très avantageuse; mais aussi il est si dangereuse, que l'Etat doit ou s'en réserver l'exercice, ou le régler de manière à en prévenir les abus.*¹

It may perhaps be said that bank-notes are essentially private paper; that the accepting of them in payment is optional; and that as they may be rejected by every one who either suspects or dislikes them, there is no room or ground for interfering with their issue! But vague generalities of this sort are entitled to very little attention. Every body knows that, whatever notes may be in law, they are, in most parts of the country, practically and in fact legal tender. The bulk of the people are without power to refuse them. The currency of many extensive districts consists in great part of country notes, and such small farmers or tradesmen as should decline taking them would be exposed to the greatest inconveniences. Every one makes use of, or is a dealer in, money. It is not employed by men of business only, but by persons living on fixed incomes, women, labourers, minors, and in short by every class of individuals; very many of whom being necessarily, from their situation in life, quite unable to form any estimate of the solidity of the different banks whose paper may be in circulation, are uniformly severe sufferers by their failure. And as the notes which come into their hands make a part of the currency or money of the country, it is evidently quite as much the duty of government, in the view of preventing these losses and the ruin they occasion, to take such steps as may be

¹ Report on the Extension of the Privilege of the Bank of France in 1840.

Money. required to make bank notes truly and substantially what they profess to be, as that it should take measures to prevent the issue of spurious coins, or the use of false or deficient weights and measures.

It would be easy to extend these remarks, but those now stated are sufficient to show that wherever notes payable on demand are allowed to circulate, their equivalency to, and immediate conversion into coin should be insured. Much diversity of opinion may exist in regard to the description of measures that should be adopted in that view; but that, whether of one sort or other, they should be made effectual to their object is indispensable to hinder the power to issue notes from being perverted to the worst purposes.

Among the schemes devised to secure the convertibility of notes into coin, the following are, perhaps, the most prominent, viz.—

Measures suggested to insure the conversion of notes into coin. Inadequacy of these measures.

I. To confine the issue of notes to joint-stock banks, or associations with large numbers of partners, each of which should be indefinitely liable for the debts of the association. At the time when this description of banks was established by the 7 Geo. IV., c. 46, it was supposed that they would prove to be of the greatest advantage, and afford that complete security to the holders of their notes, and those who entrusted them with money, that is so desirable. But everybody knows that these anticipations have been entirely disappointed, and that the history of the joint-stock banks founded under the above statute discloses some of the most flagrant instances to be met with of recklessness, imposture, and fraud. And this, after all, is only what might have been expected. The shares in many joint-stock banks are small, few being above £100, the greater number not exceeding £50, whilst many are only £25, and some not more than £10, if so much. Generally, too, it is understood, or rather it is distinctly set forth in the conditions of partnership, that not more than ten, twenty, or fifty per cent. of these shares is to be called for; so that an individual with a few pounds to spare may become a shareholder in a bank. And owing to a practice, or rather a flagrant abuse, introduced into the management of various banks, of making large advances or discounts on the credit of the stock held by shareholders, not a few individuals in doubtful or even desperate circumstances take shares in them, in the view of obtaining loans, and bolstering up their credit! The great danger arising from such banks is obvious, and when one of them stops payment, the claims on it, if ultimately made good, can be so only at the cost, and perhaps ruin, of such of its proprietors as have abstained from the abusive practices resorted to by others.

At the same time, however, it is quite plain that a joint-stock bank, provided it possess adequate capital, and is discreetly managed, may afford ample security to its shareholders and the public. And it is farther plain, in the event of its shareholders being a numerous body, comprising, as is sometimes the case, hundreds of individuals, many of whom have large fortunes, that its creditors, though exposed to immediate injury, may in the end have little or nothing to fear, even from gross mismanagement. But it is very difficult to discriminate between one variety of joint-stock banks and another. A bank may have a considerable body of proprietors; but, though the contrary opinion may prevail, few of them may be wealthy, and many mere men of straw, so that the security afforded by such a bank may be worth little or nothing. Neither is there any foundation for the notion, that because a bank has fifty or a hundred partners, it will be either richer or better managed than if it had only five or ten. In truth, the presumption seems to be quite

Money. the other way. The petty subscriptions of many may amount in the aggregate to a considerable sum, which, however, may be greatly inferior to the fortunes of a few wealthy individuals. And when the latter engage in banking, or any other sort of business, they must, if they would protect themselves from ruin, pay unremitting attention to their concerns, and act in a discreet and cautious manner. But the partners and managers of a great joint-stock company act under no such direct and pressing responsibility. "I think," said the highest authority on such subjects, "that joint-stock banks are deficient in every thing requisite for the conduct of banking business, except extended responsibility; the banking business requires peculiarly persons attentive to all its details, constantly, daily, and hourly watchful of every transaction, much more than mercantile or trading businesses. It also requires immediate, prompt decisions, upon circumstances when they arise—in many cases a decision that does not admit of delay for consultation; it also requires a discretion to be exercised with reference to the special circumstances of each case. Joint-stock banks being, of course, obliged to act through agents, and not by a principal, and therefore under the restraint of general rules, cannot be guided by so nice a reference to degrees of difference in the character or responsibility of parties; nor can they undertake to regulate the assistance to be granted to concerns under temporary embarrassment by so accurate a reference to the circumstances, favourable or unfavourable, of each case."—(*Evidence of Lord Overstone, before Committee on Bank Charter in 1840.*)

In fact, more than nine-tenths of the partners in joint-stock banks are wholly ignorant of banking business, and have nothing better to trust to than the supposed honesty and intelligence of the directors; and, even if they were acquainted with the business, the result would be nearly the same, as it would not be possible for any one, by a cursory inspection of the books of a bank (if such were permitted), to form an accurate estimate of its condition, or of the mode in which it transacted business. And hence the directors in these establishments are practically all but absolute. If they be carefully selected, and be worthy of the confidence placed in them, all goes on smoothly; and this also is the case when they are most unworthy, till they have involved the concern in inextricable difficulties! The history of the Norwich Bank, of the Northern and Central Bank, the Marylebone Bank, the Manchester Bank, the London and Eastern Bank, the Royal British Bank, the Borough Bank of Liverpool, the Western Bank of Glasgow, and a host of others, sufficiently attests the truth of what has now been stated. The responsibility of the directors to the shareholders has not been found, in any of these instances, to have been any check whatever over their frauds and improvidence. The whole paid-up capital of the Manchester Bank, amounting to about £750,000, had been wasted in the most improvident speculations; while that of the Royal British Bank and of the London and Eastern Bank had been seized upon by the directors or their dependents, and additional debts incurred, before the great body of the shareholders had the least suspicion that the companies were otherwise than prosperous!

We may observe, by the way, that the mischief occasioned by an establishment of this sort, when perverted from its proper objects and mismanaged, is not to be estimated by the ruin it entails on its partners, and probably also on its customers. It becomes in fact, a public nuisance, and entails privations on many who might be supposed to be beyond the sphere of its influence. Within the ten years ending with 1842 it was estimated that about £1,500,000 of banking capital

Money.

was wholly dissipated in Manchester and its immediate vicinity. And as nine-tenths of this enormous loss was occasioned by advances made to manufacturers who had little or no capital of their own, it is not easy to imagine what a ruinous stimulus it must have given to reckless competition, and how very injurious it must have been to parties trading on their own capital.

It is clear, therefore, that the institution of joint-stock banks affords no security that their affairs will be properly administered, and their notes uniformly paid on their being presented.

II. To insure the convertibility of bank-notes into coin, it has been proposed that they should not be issued except upon security being previously given for their payment. That, for example, an individual or company intending to issue £100,000, £200,000, or other sum of notes, should be obliged previously to deposit in the hands of a functionary appointed for the purpose, approved securities over lands, houses, stocks, or other available property for an equal amount. And it is plain that this would be in many respects an efficient measure. Under a system of this sort, adventurers without capital, and sharpers anxious to become indebted to the public, would find that the issue of notes was not a business by which they could expect to profit, and that it must be exclusively reserved for parties possessed of adequate capital.

But though a plan of this sort would effect to a considerable extent the objects in view, it has, notwithstanding, two cardinal defects, viz.—

1. In the first place, though it were fitted to secure the ultimate payment of notes, it would not secure their immediate payment, which is essential to their advantageous employment as money. The stoppage of a bank which had deposited securities would have to be officially ascertained before any steps could be taken for their sale; and after this had been done, some considerable time would have to elapse before they could be disposed of, and their produce made available for the liquidation of the notes. Most securities, too, are of fluctuating and uncertain value, and might not, even under the most favourable circumstances, realise the sums for which they were pledged. And in the event of the occurrence of a panic, or disturbed state of credit, it might be impossible immediately to convert the securities into cash, or possible only at a heavy loss. This plan is, therefore, very far from giving that effectual security for the conversion of notes into coin, which, on the first blush of the matter, it appears to afford. Latterly, it has been extensively acted upon in some parts of the United States; and there, when a bank stops payment, its notes are always sold at a discount, which, of course, varies according to the peculiar circumstances affecting each case.—(See *post*.)

2. But supposing that this plan were effectual, which it is not, to ensure the immediate convertibility of notes into coin, it is defective from its not preventing their over-issue. A paper currency is not in a sound or wholesome state, unless—1st, Each particular note or parcel of such currency be paid immediately on demand; and 2d, Unless the whole currency vary in amount and value exactly as a metallic currency would do were the paper currency withdrawn and coins substituted in its stead. The last condition is quite as indispensable to the existence of a well established currency as the former; and it is one that cannot be realised otherwise than by confining the supply of paper to a single source.

The issues of paper money should always be determined by the exchange, or rather by the influx and efflux of bullion, increasing when the latter is flowing into a country, and decreasing when it is being exported. And when the issue of paper is in the hands of a single body,

VOL. XV.

a regard to its interests will make it regulate its amount with reference to this principle. But when the power to issue notes is vested in different bodies, some of which may be little, if at all, affected by variations of the exchange, this is no longer the case. And instances have repeatedly occurred, as will afterwards be seen, of the country banks having increased their issues when the exchange was unfavourable and the currency redundant. Hence the plan of exacting securities is doubly defective, inasmuch as it neither insures the immediate conversion of notes into coin, nor prevents their over-issue.

Money.

III. The only other plan for insuring the conversion of notes into coin, or rather for keeping them on a level therewith, to which it is at present necessary to allude—consists in providing for the publicity of the affairs of the banks by which they are issued. The issues of banks, under this system, are usually made to bear some fixed proportion to their capital; the whole, or some considerable share, of which is to be paid up before the bank begins business; and monthly, quarterly, half-yearly, or annual returns are thereafter to be published, exhibiting the state of the bank, and enabling, as it is said, the public to judge whether it be safe to deal with it. But it is almost needless to say that such regulations are no protection against fraudulent dealings; and that, in reality, they are good for little, unless it be to deceive and mislead the public. It is impossible, if the managers of a bank or other association wish to make a deceptive or unintelligible return, to hinder them. And even, when they wish to make a really accurate return, they must frequently make one that is false, from their inability to estimate their bonds, bills, and other assets at their just value. But it is useless to insist on what is so very obvious. The “cooking of returns,” as it has been called, is an art that is well understood and extensively practised. Long after the capital of the British Bank had been wholly lost, and it had been precipitated into the abyss of bankruptcy, its directors did not hesitate to put forth statements, in which it was represented to be in a prosperous condition, and a division of profits recommended! And this, unhappily, is not a solitary instance. It is only one example, and that not the worst, of a very large class of cases. But such as it is, it is more than sufficient to show that it would be childish to place any confidence in the returns referred to.

It may, however, be supposed that the late Act, the Act of 1857 20 and 21 Vict. c. 54 (1857), for the punishment of against frauds committed by trustees, bankers, and others, will put an end to the practices hitherto complained of. But fraudulent returns by bankers.

though it were much to be wished that such should be the case, and though, no doubt, it will have considerable influence, it will not suffice to repress the evil. Besides making bankers and others who embezzle, appropriate, or make away with property intrusted to their care, guilty of a misdemeanour, the statute goes on to enact, “That if any director, manager, or public officer of any body corporate, or public company, shall make, circulate, or publish, or concur in making, circulating, or publishing, any written statement or account which he shall know to be false in any material particular, with intent to deceive or defraud any member, shareholder, or creditor of such body corporate or public company, or with intent to induce any person to become a shareholder or partner therein, or to intrust or advance any money or property to such body corporate, or public company, or to enter into any security for the benefit thereof, he shall be guilty of a misdemeanour.” § 8.

And it is further enacted, “That every person found guilty of a misdemeanour under this Act shall be liable,

3 L

Money.

at the discretion of the Court, to be kept in penal servitude for the term of three years, or to suffer such other punishment, by imprisonment, for not more than two years, with or without hard labour, or by fine, as the Court shall award." § 10.

It is difficult to see how, under a law of this sort, such flagrantly false statements as those put forth by the Royal British and other banks, after they were in a state of utter bankruptcy, should not subject their authors to the full penalties of the statute. But villany is fertile in resources; and no severity of punishment has ever been found to be effectual for the suppression of crime. Though it may be fairly presumed that the "cooking of returns" will be less frequent, and less glaring in time to come than formerly, it would be idle to expect that it should ever be wholly put down. And, as already seen, even when the directors of a bank are so disposed, it will frequently be out of their power to lay before the public a really true statement of their affairs. It is plain, then, that this so-called publicity affords nothing approaching to that undoubted and unquestionable guarantee which should be required from all parties and associations empowered to issue notes.

But the difficulties in the way of insuring the conversion of the latter into coins, though great, are not insuperable. A plan, originally suggested by Lord Overstone, and adopted and carried into effect by Sir Robert Peel, has been found to be quite effectual to secure this grand object. And it has the additional and important recommendation, of having done this without subjecting the public to any sensible inconvenience.

But before entering into an exposition of the plan referred to, it will be necessary to premise some details with regard to the constitution and action of the existing banks.

SECT. II.—*Banks of Deposit and Banks of Issue. Principles on which they are established.*

Banks of deposit and issue.

Banks are commonly divided into banks of deposit and banks of issue; that is, banks that take care of other people's money, and banks that issue money of their own. But there are few banks of issue that are not at the same time banks of deposit; and the latter are farther divisible into two great classes, viz., those who do and those who do not issue the money of their customers. The banking companies established in this country belong to the first class; while the old Bank of Amsterdam did, and the existing Bank of Hamburg does, belong to the second class.

Advantages of bankers.

Instead of keeping money in their own houses, where it would be exposed to various accidents, and to the attacks of thieves and robbers, most people wisely commit it to the care of a banker, and avail themselves of his services in receiving and making payments on their account. They send to their banker such sums of money as they may happen to receive, and all bills and drafts payable to them; and he becomes responsible for their amount, for the regular presentation of the bills for acceptance and payment, and for their proper noting, if not accepted or paid. It is also the practice for parties

Money.

who have an account at a banker's, to make all considerable payments by cheques payable by him. As the discharge of these functions involves considerable risk and expense, it is usual for bankers, either to charge a per centage for their trouble, or to stipulate that the parties dealing with them shall keep an average balance of cash in their hands corresponding to the amount of business transacted in their behalf. In this way business is carried on with safety, ease, and despatch; and at much less expense than it would be if individuals kept their own money, and made their own payments.

Of the sums paid into banks, some are intended to meet the cheques and orders drawn against them in the ordinary course of business; while others are sent rather for safe custody, to be retained, till opportunities be found for their investment. The former are generally placed under what are called *drawing*, and the latter under *deposit* accounts. But there is no difference between the two, except that the sums in deposit accounts are usually permitted to lie for longer periods, without being operated upon or called up. Such portions of the one or the other as the bankers do not retain in their coffers to meet the usual demands of their customers, they employ in the discount of bills, or in making advances of one sort or other, generally at short dates, to those who require them, and in whom they think they may confide.

This last is one of the most important functions performed by banks of deposit. They become, as it were, receptacles or reservoirs into which the surplus or unemployed capital of the surrounding districts is collected, and from which it is again distributed to those who want it. And it may be proper to observe, that the bankers do not always, nor perhaps even most commonly, confine their advances to those who can give security for their repayment. On the contrary, they are often more influenced in making loans by their knowledge of the conduct, the intelligence, and the pursuits of the parties, than by anything else. And it frequently happens that industrious, frugal, and enterprising young men, who have no guarantee to offer save their character, obtain advances that would be denied to wealthier, but otherwise less trustworthy parties.¹ But without insisting on these considerations, which, however, are not a little important, it is manifest that those who have capital to lend, and those who wish to borrow, are equally indebted to the agency of the bankers, who while they enable these great classes mutually to assist each other, contribute to increase the public wealth by facilitating the flow of capital into the most productive channels.

But, however great, this advantage is not to be exaggerated. Though banks afford valuable assistance in the collection and distribution of capital, it must not be supposed, as is often done, that they have any direct influence over its formation. That is the joint effect of industry and economy—the former in producing convenient and desirable articles, and the latter in saving and preserving them for future use. Credit is neither more nor less than the transfer of money or other valuable produce from one set of individuals called lenders, to another set called borrowers

Credit, definition of.

¹ On this, as on most other points, the late evidence of Lord Overstone is highly instructive.

Quest. But, generally speaking, persons who have no capital, have very little opportunity of raising money have they? *Ans.* That certainly is not so. The whole principle of banking is to afford capital—to transfer it from the inactive accumulator to the active and energetic person who wants the capital. The banker is the go-between, who receives deposits on the one side, and on the other applies those deposits, intrusting them, in the form of capital, to the hands of active, energetic persons, who, he thinks, will make a good use of it.

Quest. Who have no security to give? *Ans.* Who have in many instances no security to give, except their character, and skill, and talent, of which the banker forms his judgment.

Quest. To persons of character who have no other security to give? *Ans.* To persons of character who, in some cases, have no security to give; but who, in all cases, have no security to give equal to the amount advanced to them, except that best form of security, their character, their energy, and their prudence.—*Min. of Evidence*, p. 348.

Money.

—a transfer which is greatly facilitated by the establishment of banks. And as there can be no reasonable doubt that those who borrow have, in the majority of instances, better means of employing capital with advantage than those by whom it is lent, its transference from the one to the other will, in so far as this presumption is realised, be publicly advantageous. But this is the entire extent of the beneficial influence of what is called credit; and when it happens, as is too often the case, to divert capital into the pockets of knaves and gamblers, it is disadvantageous. No doubt we frequently hear of great undertakings being carried on by means of credit; but such statements are entirely false and misleading. They will, indeed, be uniformly found, when analysed, to mean only that the undertakings are carried on by means of borrowed capital. Credit is impotent to produce anything whatever. It is in fact a mere name for the trust reposed by a lender in a borrower. To call it capital is as much an abuse of language as it would be to call weight colour, or colour weight. It may transfer money or produce from A to B, or from C to D, but that is all that it either does or can do. When credit is said to be high, nothing is really meant save that those who have money or capital to lend have great confidence in the borrowers, and conversely when credit is said to be low.

Banks sometimes encourage gambling and over-trading.

Banks, when not conducted by men of probity, skill, and caution, are very apt to excite and inflame a spirit of speculation and gambling. They do this by furnishing speculators with loans and discounts, by means of which they are not enabled merely, but tempted to engage in hazardous enterprises. And for a time, or while the process is going on, everything wears an air of prosperity; and those old-fashioned houses, as they are called, that carry on a legitimate business on capital of their own, are frequently undersold and driven from the market by the competition of adventurers, trading on the funds of others, ready to encounter any risk, and living in the greatest splendour. But at length the thing is overdone, the bubble bursts, the worthless machinery of fictitious bills, rediscounts, and so forth, is exposed, and the tragi-comedy is wound up by the offer of a composition of some 1s. or 2s. per pound. Bankers and money dealers who employ the money entrusted to their care in so reckless a manner, are fitter for Newgate than for the situations they so unworthily fill. It would be a great stretch of charity to suppose that advances of the kind now alluded to can be wholly the result of imprudence. Bankers have peculiar means at their disposal by which to become acquainted with the character, position, and capabilities of those who apply to them for advances. And it is their duty to avail themselves of these means to distinguish between the careful and the improvident or reckless trader—between the man who may and the man who may not be trusted. It is difficult to believe, provided they make the necessary inquiries, that they should be often or greatly deceived in their judgment of individuals; and, provided they act with due caution, they will never so far commit themselves, even with the most respectable firms, as to endanger their own establishment in the event of the failure of the latter. Bankers may risk their private fortunes, if they have any, as they please, but they are not entitled to risk the money of their constituents by making advances to equivocal parties, and especially to those who are notoriously overtrading. It is impossible, perhaps, to bring an abuse of this sort within the meshes of the penal law, but it cannot be too strongly condemned in the opinion of the public. There

Money.

is nothing about which people should be so cautious as the employment of bankers; and high character, experience, and reputation for prudent management, ought always to have the preference over fair promises and prospectuses, even when the latter are backed by offers of high interest.

The private bankers of London have not been, until recently, in the habit of allowing interest on deposits, though in special cases it was sometimes done. But in Scotland, and also in many parts of England, it has been long the practice to pay an interest on deposits of from one to two per cent. less than the market rate at the time. And the joint-stock banks set on foot in the metropolis since 1826, having introduced the practice of giving interest on deposits, provided a certain notice (generally from three to eight days) be given before they are withdrawn, very large sums have been, especially during the last ten years, deposited in these establishments. Most private banks have been compelled, in order to maintain their position, to adopt in a greater or less degree the same system. There can, indeed, be little doubt that it will, in no very lengthened period, become universal, and that the amount of deposits will be progressively and largely augmented.

By bringing, as it were, the advantages of savings' banks, without any of their limitations, within reach of all classes, of the middle and upper as well as of the lower, this system is, in many respects, highly advantageous. It may, indeed, be doubted whether any means could be devised more likely to generate and diffuse a spirit of economy. Unhappily, however, its advantages are alloyed by the formidable disadvantage of its involving a great amount of insecurity and hazard.

Banks that give interest on deposits must employ the balance at their disposal so as to realise that interest, plus a profit to themselves. Investment is not optional with them, it is indispensable; and they cannot, in seeking investments, look to security only. Profit must be in their estimation as great, or even a greater consideration. But profit and risk are inseparable, and are always directly proportioned to each other; and hence it is, that in periods of discredit, or when a revulsion occurs, suspicions may be expected to arise in regard to the solidity of deposit banks, especially of those that pay high rates of interest on the sums committed to their custody. These suspicions may frequently, no doubt, be very ill-founded; but if they be entertained, the result will be nearly the same. This was exemplified by what took place the other day in Glasgow. There a run, partly for payment of notes, but more for deposits, compelled two great joint-stock banks to suspend payments, of whose solvency, notwithstanding their gross mismanagement, no reasonable doubt could be entertained; and led to a crisis that has had the most serious consequences.

Dangers incident to the deposit system.

It is difficult to know how to ward off such contingencies; but it nevertheless seems to be indispensable that something should be done in that view, otherwise we may be said to be always exposed to the most tremendous risks. It may not be practicable to form an accurate estimate of the amount now held as deposits by bankers and money-dealers in Great Britain only; but if we take the entire sum at about two hundred millions, we shall probably be within and not beyond the mark. And of this vast sum more than a half is payable "at call," and more than three-fourths within ten days. But everybody knows that such payments are practically impossible. And hence it is plain, that in the event, which may any day occur, of a bank with

Money.

a large amount of deposits getting into difficulties, or of any circumstance occurring that should occasion a distrust of the system and a general panic, the whole fabric would fall to pieces, and we should have an universal smash.

This appears to be as unsatisfactory a state of things as can well be imagined. But *de republica nil desperandum*. Though formidable, the evil is not insuperable; and the dangers referred to are so great and imminent, that no time should be lost in adopting measures by which they may be either obviated or mitigated. Explosions of the credit system are, in the commercial and financial, what explosions of gunpowder are in the physical world. And it would seem to be quite as necessary to endeavour to lessen the frequency and violence of the former as of the latter. Hence we think it would be good policy to enact, that all sums *bearing interest*, in the hands of bankers, discount-brokers, and money-dealers generally, should not be legally demandable without a month or six weeks' notice. A regulation of this sort would not interfere with anything that is valuable in the existing system, while it would confer on it some portion of that solidity of which it is at present so miserably deficient. It would protect all classes against the effects of sudden and unreasonable fears and panics. It would give time to the borrowers to collect their resources; and to the depositors calmly to inquire into the character and situation of those to whom they had entrusted their money. This may not be enough; but some such measure as this appears to be indispensable for the security and protection of the public.

Notes deposited in banks not the property of the depositors.

It has sometimes been contended that the notes and monies deposited in banks by private parties continue to be their property, and are as really a portion of their money as the notes or sovereigns which they retain in their tills or their pockets. The place where it is kept is different; but, except in this respect, the money which they have lodged in and that which they have out of banks, is said to be, to all intents and purposes, identical. But though specious, this statement is entirely fallacious. The money which depositors lodge in banks forms a part of the money of the country; but after its lodgment in them it ceases to belong to, or to make a part of the property or money of the depositors. They have consigned it to banking establishments, and acquired credits in its stead; that is, they have acquired the *right* to draw upon and receive equal sums of money from these establishments. But everybody knows that the right to a thing is not the thing itself, but something altogether different. A banker who owes a million or other sum to depositors, might regard himself as being in a sufficiently secure state, if, according to circumstances, he had a third, a fourth, or a fifth part of that sum in notes and gold in his till to answer the demands of the depositors, while he employed the reserve in advances to others. Hence it is plain that bank credit and money have nothing in common. Those who confound things that are so very different can have no clear apprehension either of the one or the other.

It is on the distinction between money and deposits or credits, that the business of banking really depends. It is a business by which a small amount of money is made to supply a large amount of credit, the profits of the bankers arising from the use of the money so economised. The Bank of England, for example, often holds more than twenty millions of public and private deposits, while she is considered to be in a perfectly safe and sound position if she have in the till of her banking department five millions, or even less, in notes and coins.

It is hardly necessary, after these statements, to observe that the profit made by bankers in employing part of the money committed to their custody is extrinsic to, and independent of, any profits which they may realise on capital of their own. "Such banks," to use the words of Mr Ricardo, "would never be established if they obtained no other profits than those derived from the employment of their own capital. Their real advantage commences only when they begin to employ the capital of others."—(*Economical and Secure Currency*, p. 87.)

But we are not thence to conclude that it is indifferent whether such banks have or have not independent capitals of their own. That would be the greatest of errors. Unless it have a command of capital proportioned in some degree to the extent of its business, those who deposit their money in a bank have but slender security for its payment. For if bankers make improvident or injudicious advances, if the securities in their possession be discredited, or difficulties of any kind arise in the conduct of their business, those who have no capital, or but little of their own, may be obliged to stop payment, when more opulent firms may be but little affected by the like circumstances. Much, no doubt, must always depend on the character and knowledge of the parties. But no amount of skill or caution can ever fully compensate for the want of adequate capital. It is the sheet-anchor of security, the only real and substantial guarantee to which the ordinary creditors of a bank have to look. When such capital has been accumulated by the bank, it shows that its affairs have been well managed, and raises a strong presumption in its favour; and when it has devolved on the partners by inheritance, or been bequeathed to them in legacies, the fair inference would seem to be, that they will not (unless they be mere fools, unworthy of any kind of confidence) rashly compromise its security by engaging in questionable proceedings.

Money.

Necessity of capital to the security of banks.

It has been sometimes proposed to allow banks to be constituted with limited liability. But that is in every case a vicious principle, lessening the natural responsibility under which every man ought to act, and tempting parties to engage in all manner of desperate adventures. In banking, such a principle would be especially mischievous; for it is a business that requires great caution and prudence—the very virtues with which the principle of limited liability is most at variance. It may, indeed, be said that the numerous instances of mismanagement and embezzlement that now prevail, show that even the principle of indefinite liability is not enough to make joint-stock banks be conducted prudently and honestly. But, however defective, still it is the only principle on which any stress can be safely laid, and the instances referred to, bear, after all, but a small proportion to those of an opposite description. The great majority of banks are discreetly and faithfully managed. And if knavery and folly be sometimes found to prevail where every partner is deeply interested in their prevention, and is liable to the last farthing he possesses for the consequences, the fair presumption is, that they would be ten times more prevalent were the partners liable only for the amount of their shares in the bank. To suppose the contrary would be a contradiction; it would be equivalent to supposing that a man is to be as much interested in the safety of £10 or £100, as of £1000 or £10,000, or of his entire fortune, however great it may be.

Limited liability, disadvantages of.

Whatever else may be the effect of the late disclosures of mismanagement, fraud, and robbery, on the part of the directors and secretaries of joint-stock banks, it can hardly fail to make the partners in those associations more alive to the dangers of their situation, and to convince them, that

Money. if they would provide for their own safety, they must be more cautious than hitherto in regard to the persons they elect to fill these situations, and less disposed to take their statements for granted. Such, however, is the carelessness of most people, even in regard to those matters which most nearly concern them, that these anticipations, though reasonable, may not be fully realised. But, in the case of banks with limited liability, they must be sanguine indeed, who look for any improvement. The partners in these associations have no sufficient interest in their prosperity to make them take any unusual trouble about the way in which they are conducted, and they neither fear ruin, nor even any considerable inconvenience, from their failure. The chances, consequently, are ten to one that their managers will be left without let or hindrance to pursue their own schemes; and, when such is the case, what but abuse can be expected to be the result?

But it is argued, that whatever may be the influence of the present system on the partners in the existing banks, were companies with limited liability established, the depositors would be on their guard, and would not trust them with their money, unless they were well assured of their solidity. But, in truth and reality, they never can have any assurance of the sort on which it would be safe to rely. A bank with limited liability might have, or pretend to have, a large capital. And supposing it really had such a capital in the current year, that may not be the case in the next, or in any subsequent year. And yet as the public can know nothing certain of the bank's losses, its credit may not be impaired, and deposits may be pressed upon it after it is really insolvent. In such cases the public is helpless; and if the indefinite responsibility of the partners in banks be not enough to make them look to their proper management, it would be worse than idle to depend in any degree on the fears or interests of the depositors. This is not a matter about which there needs be any speculation. The experience of the United States is decisive of the question. In the Union, the banks are all, or nearly all, established under a system of limited liability, and, notwithstanding their insecurity, and their perpetually recurring insolvency, they always hold large sums in deposit. Promises, professions, the bait of high interest,¹ and the confidence placed by every one in his superior sagacity and good fortune, fill the coffers even of the establishments least worthy of credit. And such, no doubt, would be the case in England, were a like system established amongst us. But what, under such circumstances, would be the situation even of a well managed bank, were any suspicions to be entertained of its credit? The rush would be tremendous; for every body would reasonably conclude, that if he did not succeed by pressing forward with "hot haste" in getting payment of his deposit, the chances were ten to one he would get little or nothing. He has no proprietary body to which to look for payment of his claims; and if the doors were once shut against him, he could hardly expect more than some miserable dividend at some distant term.

Proposal to enforce dis- counts— absurdity of. Among the many proposals submitted to the consideration of the Bank Committee of 1857, perhaps the most extraordinary was that which assumed that something was wrong with the currency whenever any difficulty was experienced in the discounting of bills originating in real transactions, and that means should be found, in some way or other, to compel the discount of such bills. It may excite surprise that such a proposal

should have been seriously made, and still more, that it should have been listened to and published. Luckily it cannot be called "perilous nonsense," its folly being so very obvious, that it can impose on none. The discount of bills is an advance or loan of capital equivalent to their value till they become due. That advance is now usually made in paper; but as that paper is really equivalent to gold, it might, were it not for the greater convenience of the present practice, be as well made in coin or in commodities. The amount of the currency has, in truth, nothing whatever to do with the greater or less facility of discounting. That depends entirely on the amount of capital applicable to such purpose, compared with the amount of bills offered for discount. The settlement of such transactions is, if anything can be, a matter to be left to the free and uncontrolled arbitrament of the parties. Whether a bill be discounted at five or ten per cent, or not discounted at all, is, in a public point of view, of no importance. When a capitalist declines to make an advance, whether on a bill or anything else, the presumption is that he has good reasons for his refusal. But, whether good or bad, the public has no right to interfere in the matter; and any attempt it might make to interfere would be attended with ruinous results. Those who suppose that the facility of discounting depends on the magnitude of the issues of paper, would do well to recollect that in Holland, which for a lengthened period had a very extensive commerce, and where paper was unknown, the rate of discount was always very low. And while such was the case in Holland, every body knows that in the United States, which have some 1300 banks for the issue of notes, the rate of discount is usually very high, and sometimes exorbitantly so.

The business of banking was not introduced into London till the seventeenth century. It was at first conducted by the goldsmiths, who lent the money lodged in their hands for security to government and individuals. In the course of time the business came to be conducted by houses who confined themselves to it only, and nearly in the mode in which we now find it. From 1708, as already stated, down to 1826, with the exception of the Bank of England, no company with more than six partners could be established, either in London or anywhere else in England and Wales, for conducting banking business; and a very large portion of that business is still conducted in the metropolis by firms with a small number of partners, or by what are called private banks.

In 1775, the London, or rather the "city" bankers, established the "clearing-house." This is a house to which each banker who deals with it is in the habit of daily sending a clerk, who carries with him the various bills and cheques in the possession of his house that are drawn upon other bankers; the practice formerly being to exchange them for the bills and cheques in the possession of those others that were drawn upon his constituents, and to pay the balance on the one side or the other in cash or Bank of England notes. By this means the bankers connected with the clearing-house were enabled to settle transactions to the extent of several millions a day, by the employment of not more, at an average, than from £200,000 to £500,000 in cash or Bank of England notes.

Latterly, however, the arrangements connected with the clearing-house have been so much simplified and improved, that neither notes nor coins are any longer

¹ "Vulgus ad magnitudinem beneficiorum aderat: stultissimus quisque pecuniis mercabatur."—Tacit. Hist., lib. iii. cap. 55.

Money. required in settling the largest transactions. The clearing-house itself and the various banking firms connected with it, have accounts at the Bank of England; and the balances that were formerly settled by a money payment are at present settled by transfers from one account to another. The saving of money in the adjustment of large transactions occasioned by this and other contrivances, accounts for the fact, that the proportion of notes of £20 and upwards issued by the bank has considerably declined of late years, while that of £5 and £10 notes, which are used in ordinary dealings, has been materially increased.

Money. largely, may be productive of much loss or inconvenience to its creditors. But if the paper in circulation be equivalent to gold, such bankruptcies cannot affect either the quantity or value of money, and are, therefore, directly injurious only to the parties concerned.

But though such be the direct effects of the bankruptcies of deposit banks, their indirect effect, by propagating panics and runs on other banks, may be most disastrous. And to prevent their mischievous influence in this respect, it would be good policy, as already seen, to require a month's or six weeks' notice to make deposits bearing interest legally demandable.

Security afforded by banks of deposit. The security afforded by a bank of deposit is a matter as to which there must always be more or less of doubt. When, indeed, a banking company confines itself to its proper business, and does not embark in speculations of unusual hazard, or from which its funds cannot be easily withdrawn, it can seldom fail, except in periods of panic or general distrust, of being in a situation to meet its engagements; whilst the large private fortunes that frequently belong to the partners afford those who deal with it an additional guarantee. Much, however, depends on the character of the parties, on their living within or beyond their incomes, and on a variety of circumstances with respect to which the public can never be correctly informed; so that though there can be no doubt that the security afforded by many banks of deposit is of the most unexceptionable description, this may not be the case with others.

Not necessary for the State to provide for the security of depositors. All joint-stock banks, or banks having more than six partners, whether for deposit and issue, or for deposit merely, are ordered, by the Act 3 and 4 Will. IV. cap. 83, to send quarterly returns of the number and names of their partners to the stamp-office. But there was no good reason why similar returns should not, and several why they should, be required from *all* banks; and this having been done by the Act 7 and 8 Vict. c. 32, which also provides for their publication, little if any farther interference would seem to be required with banks not issuing notes. There is in this respect a wide difference between them and banks of issue. It is the duty of government to take care that the value of the currency shall be as invariable as possible; but it has never been pretended that it is any part of its duty to inquire into the security given by the borrowers to the lenders of money, any more than into the security given by the borrowers to the lenders of any thing else. Government obliges a goldsmith to have his goods stamped, this being a security to the public that they shall not be imposed on in buying articles of the quality of which they are generally ignorant; but it does not require that the persons to whom the goldsmith sells or lends his goods should give him a guarantee for their payment. This is a matter as to which individuals are fully competent to judge for themselves; and there is no good reason why a lender or depositor of bullion or notes should be more protected than a lender or depositor of timber, coal, or sugar. Gold being the standard or measure of value, government is bound to take effectual precautions that the currency shall truly correspond in the whole and in all its parts with that standard; that every pound note shall be worth a sovereign; and that the amount and value of the aggregate notes in circulation shall vary exactly as a gold currency would do were it substituted in their stead. But if A trust a sum of money in the hands of B, it is their affair, and concerns none else. Provided the money afloat correspond with the standard, it is of no importance, in a public point of view, into whose hands it may come. The bankruptcy of a deposit bank, like that of a private gentleman who has borrowed

Deposit banks which do not employ the money of the depositors. The other description of banks of deposit, or those which do not employ the funds in their hands, or engage in any sort of business, are established without any view to profit, that they may secure the money, and facilitate the transactions of those who deal with them. The latter obtain *bank credits* or *bank money*, equivalent to the sums they deposit in the bank; and as the principal traders in towns where such a bank is established belong to it, each has a bank credit, and their payments are made without the intervention of money, by writing off so much from the credit or account of one to the credit or account of another. It is only in the event of a person having to pay money to a stranger that he has any motive to withdraw any portion of his deposit from the bank. An institution of this sort is, to those who deal with it, what the clearing-house is to the London bankers. Its expenses are usually defrayed either by a small fee charged on every transfer of bank credit from one individual to another, or by a charge on the coin or bullion deposited, or both.

A bank of this sort can never, unless its agents act dishonestly, be involved in debt, or in any kind of difficulty. The constitution of the Bank of Amsterdam was in so far vicious that it was not managed by parties interested in its welfare; that is, by agents chosen by the depositors. On the contrary, it was managed in the most secret manner by those who happened to be magistrates of the city, whether they were or were not depositors. And they, in violation of their oaths, privately lent to others a large portion of the funds deposited in the bank. But a proceeding of this sort is hardly possible in the case of a properly constituted deposit bank, like that established in Hamburg. For in the latter the managers are appointed for short periods by the depositors, who, of course, endeavour to select the most trustworthy persons. And though it be necessary that the strictest secrecy should be kept in regard to the accounts of individuals in the bank, its affairs are otherwise transacted with sufficient publicity, while the deposits in its coffers may be withdrawn at any moment.

Notice of banking. The trade or business of a banker has probably existed in all civilised countries in all ages. The bankers of Greece (*τραπεζίται*) and Rome (*argentarii, mensarii, nummularii*) exercised nearly the same functions as those of the present day, except that they do not appear to have issued notes. They received money on deposit, to be repaid on demands made by cheques or orders, or at some stipulated period, sometimes paying interest for it, and sometimes not. Their profits arose from their lending the balance at their disposal, at higher rates of interest than they allowed the depositors. They were also extensively employed in valuing and exchanging foreign monies for those of Athens, Corinth, Rome, &c., and in negotiating bills of exchange. In general they were highly esteemed, and great confidence was placed in their integrity. The rate of interest charged by the bankers

Money. was sometimes very high, but that was not a consequence, as has been alleged, of their rapacity, but of the defective state of the law, which, as it gave every facility to debtors disposed to evade payment of their debts, obliged the bankers to guarantee themselves by charging a proportionally high rate of interest.¹ In modern times the business of banking and exchange was, for a while, almost entirely engrossed by the Jews and the Lombards of Italy.

SECT. III.—*Bank of England, Account of.*

Establishment and History of the Bank of England.

The Bank of England, which has long been the principal bank of deposit and circulation, in this country and in Europe, was founded in 1694. Its principal projector, Mr William Paterson, an enterprising and intelligent Scotch gentleman, was afterwards engaged in the ill-fated colony at Darien. Government being at the time much distressed for want of money, partly from the defects and abuses in the system of taxation, and partly from the difficulty of borrowing, because of the supposed instability of the revolutionary establishment, the bank grew out of a loan of £1,200,000 for the public service. The subscribers, besides receiving eight per cent. on the sum advanced as interest, and £4000 a year as the expense of management, in all £100,000 a year, were incorporated into a society denominated the Governor and Company of the Bank of England. The charter is dated the 27th of July 1694. It declares, amongst other things, that they shall "be capable, in law, to purchase, enjoy, and retain to them and their successors, any monies, lands, rents, tenements, and possessions whatsoever; and to purchase and acquire all sorts of goods and chattels whatsoever, wherein they are not restrained by Act of Parliament; and also to grant, demise, and dispose of the same.

"That the management and government of the corporation be committed to the governor and twenty-four directors, who shall be elected between the 25th of March and the 25th day of April each year, from among the members of the company duly qualified.

"That no dividend shall at any time be made by the said governor and company, save only out of the interest, profit, or produce arising by or out of the said capital stock or fund, or by such dealing as is allowed by Act of Parliament.

"They must be natural-born subjects of England, or naturalised subjects; they shall have in their own name, and for their own use, severally, viz. the governor at least £4000, the deputy-governor £3000, and each director £2000, of the capital stock of the said corporation.

"That thirteen or more of the said governors and directors (of which the governor or deputy-governor must be always one) shall constitute a court of directors, for the management of the affairs of the company, and for the appointment of all agents and servants which may be necessary, paying them such salaries as they may consider reasonable.

"Every elector must have, in his own name and for his own use, £500 or more capital stock, and can only give one vote. He must, if required by any member present, take the oath of stock, or the declaration of stock in case he may be one of the people called Quakers.

"Four general courts to be held in every year, in the months of September, December, April, and July. A general court may be summoned at any time, upon the requisition of nine proprietors duly qualified as electors.

Money. "The majority of electors in general courts have the power to make and constitute by-laws and ordinances for the government of the corporation, provided that such by-laws and ordinances be not repugnant to the laws of the kingdom, and be confirmed and approved, according to the statutes in such case made and provided."

The corporation is prohibited from engaging in any sort of commercial undertaking other than dealing in bills of exchange, and in gold and silver. It is authorised to advance money upon the security of goods or merchandise pledged to it; and to sell by public auction such goods as are not redeemed within a specified time.

It was also enacted, in the same year in which the bank was established, by statute 6 William and Mary, c. 20, that the bank "shall not deal in any goods, wares, or merchandise (except bullion), or purchase any lands or revenues belonging to the crown, or advance or lend to their majesties, their heirs or successors, any sum or sums of money, by way of loan or anticipation, or any part or parts, branch or branches, fund or funds of the revenue, now granted or belonging, or hereafter to be granted, to their majesties, their heirs and successors, other than such fund or funds, part or parts, branch or branches of the said revenue only, on which a credit of loan is or shall be granted by Parliament." And in 1697 it was enacted, that the "common capital or principal stock, and also the real fund, of the governor and company, or any profit or produce to be made thereof, or arising thereby, shall be exempted from any rates, taxes, assessments, or impositions whatsoever, during the continuance of the bank; that all the profit, benefit, and advantage from time to time arising out of the management of the said corporation, shall be applied to the uses of all the members of the said association of the governor and company of the Bank of England, rateably and in proportion to each member's part, share, and interest in the common capital and principal stock of the said governor and company hereby established."

In 1696, during the great recoinage, the bank was involved in great difficulties, and was even compelled to suspend payment of her notes, which were at a heavy discount. Owing, however, to the judicious conduct of the directors, and the assistance of the government, the bank got over the crisis. But it was at the same time judged expedient, in order to place her in a situation the better to withstand any adverse circumstances that might afterwards occur, to increase her capital from £1,200,000 to £2,201,171. In 1708, the directors undertook to pay off and cancel one million and a half of exchequer bills they had circulating two years before, at four and a half per cent., with the interest upon them, amounting in all to £1,775,028, which increased the permanent debt due by the public to the bank, including £400,000 then advanced in consideration of the renewal of the charter, to £3,375,028, for which they were allowed six per cent. The bank capital was then also doubled, or increased to £4,402,343. But the year 1708 is chiefly memorable in the history of the bank, for the Act previously alluded to, which declared, that during the continuance of the corporation of the Bank of England, "it should not be lawful for any body politic, erected or to be erected, other than the said governor and company of the Bank of England, or of any other persons whatsoever, united or to be united in covenants or partnership, exceeding the number of six persons, in that part of Great Britain called England, to borrow, owe, or take up any sum or sums of money on their bills or notes payable on demand, or in

¹ Boeckh's *Political Economy of Athens*, i. 168, &c.; *Voyage d'Anacharse*, cap. 55, *passim*; *Smith's Dictionary of Greek and Roman Antiquities*, voce *Argentarii*, &c.

Money. any less time than six months from the borrowing thereof." This proviso, which had a powerful operation on banking in England, is said to have been elicited by the Mine-Adventure Company having commenced banking business, and begun to issue notes.

The charter of the Bank of England, when first granted, was to continue for eleven years certain, or till a year's notice after the 1st of August 1705. The charter was further prolonged in 1697. In 1708, the bank having advanced £400,000 for the public service, without interest, the exclusive privileges of the corporation were prolonged till 1733. And in consequence of various advances made at different times, the exclusive privileges of the bank have been continued by successive renewals, till the first of August 1855, with the proviso that they may be cancelled on a year's notice to that effect being given after the said 1st of August 1855.

We subjoin an account of the successive renewals of the charter, of the conditions under which these renewals were made, and of the variations in the amount and interest of the permanent debt due by government to the bank, exclusive of the dead weight.—(See following page.)

Capital of
the Bank.

The capital of the bank on which dividends are paid has never exactly coincided with, though it has seldom differed very materially from, the permanent advance by the bank to the public. We have already seen that it amounted in 1708 to £4,402,243. Between that year and 1727 it had increased to near £9,000,000. In 1746 it amounted to £10,780,000. From this period it underwent no change till 1782, when it was increased eight per cent., or to £11,642,400. It continued stationary at this sum down to 1816, when it was raised to £14,553,000, by an addition of twenty-five per cent. from the profits of the bank, under the provisions of the Act 56 Geo. III. c. 96. The Act for the renewal of the charter 3 and 4 Will. IV. c. 98, directed that the sum of £3,671,700, being the fourth part of the debt due by the public to the bank, should be paid to the latter, allowing her, if she chose, to deduct it from her capital. But that has not been done; and after sundry changes, the capital of the bank amounts, as formerly, to £14,553,000.

Crisis of
1745.

The Bank of England has been frequently affected by panics amongst the holders of her notes. In 1745 the alarm occasioned by the advance of the Highlanders, under the Pretender, as far as Derby, led to a run upon the bank; and in order to gain time to effect measures for averting the run, the directors adopted the device of paying in shillings and sixpences! But they derived a more effectual relief from the retreat of the Highlanders, and from a resolution agreed to at a meeting of the principal merchants and traders of the city, and very numerous signed, declaring the willingness of the subscribers to receive bank-notes in payment of any sum that might be due to them, and pledging themselves to use their utmost endeavours to make all their payments in the same medium.

Crisis of
1780.

During the tremendous riots in June 1780, the bank incurred considerable danger. Had the mob attacked the establishment at the commencement of the riots, the consequences might have proved fatal. But they delayed their attack till time had been afforded for providing a force sufficient to insure its safety. Since that period a considerable military force is nightly placed in the interior of the bank, as a protection in any emergency that may occur.

Crisis of
1797.

The year 1797 is the most important epoch in the recent history of the bank. Owing partly to events connected with the war in which we were then engaged; to loans to the Emperor of Germany; to bills drawn on the

treasury at home by the British agents abroad; and partly, and chiefly, perhaps, to the advances most unwillingly made by the bank to government, which prevented the directors from having a sufficient control over their issues, the exchanges became unfavourable in 1795, and in that and the following year large sums of specie were drawn from the bank. In the latter end of 1796 and beginning of 1797, considerable apprehensions were entertained of invasion, and rumours were propagated of descents having been actually made on the coast. In consequence of the fears that were thus excited, runs were made on the provincial banks in different parts of the country; and some of them having failed, the panic became general, and extended itself to London. Demands for cash poured in upon the bank from all quarters; and, on Saturday the 25th of February 1797, she had only £1,272,000 of cash and bullion in her coffers, with every prospect of a violent run taking place on the following Monday. In this emergency, an order in council was issued on Sunday the 26th, prohibiting the directors from paying their notes in cash until the sense of Parliament should be taken on the subject. And after Parliament met, and the measure had been much discussed, it was agreed to continue the restriction till six months after the signature of a definitive treaty of peace.

As soon as the order in council prohibiting payments in cash appeared, a meeting of the principal bankers, merchants, traders, &c. of the metropolis, was held at the Mansion-house, when a resolution was agreed to, and very numerous signed, pledging, as had been done in 1745, those present to accept, and to use every means in their power to make bank-notes be accepted, as cash in all transactions. This resolution tended to allay the apprehensions that the restriction had excited.

Parliament being sitting at the time, a committee was immediately appointed to examine into the affairs of the bank; and their report put to rest whatever doubts might have been entertained with respect to the solvency of the establishment, by showing, that at the moment when the order in council appeared, the bank was possessed of property to the amount of £15,513,690, after all claims upon her had been deducted.

Much difference of opinion has existed with respect to the policy of the restriction in 1797; but, considering the peculiar circumstances under which it took place, its expediency seems abundantly obvious. The run did not originate in any over-issue of bank paper, but grew entirely out of political causes. So long as the alarms of invasion continued, it was clear that no bank paper immediately convertible into gold would remain in circulation. And as the bank, though possessed of ample funds, was without the means of instantly retiring her notes, she might, but for the interference of government, have been obliged to stop payments; an event which, had it occurred, might have produced consequences fatal to the public interests.

The error of the government did not consist in their coming to the assistance of the bank, but in continuing the restriction after the alarm of invasion had ceased, and there was nothing to hinder the bank from safely reverting to specie payments.

It had been generally supposed, previously to the passing of the Restriction Act, that bank-notes would not circulate unless they were immediately convertible into cash. But the event showed, conformably to the principles already stated, that this was not really the case. Though the notes of the Bank of England were not, at the passing of the Restriction Act, declared by law to be legal tender, they were rendered such in practice, by being received

as cash in all payments on account of government, and by the vast majority of individuals. For the first three years of the restriction, their issues were so moderate, that they not only kept on a par with gold, but actually bore a small premium. But in 1801, 1802, and 1803, they were so much increased that they fell to a discount of from 8 to 10 per cent. In 1804 they again recovered their value; and from that year to 1808, both inclusive, they were at a discount of $2\frac{1}{2}$ per cent. In 1809 and 1810, however, the directors appear to have embarked on a new course, and to have entirely lost sight of the principles by which their issues had previously been governed; for the average amount of bank-notes in circulation, which had not exceeded $17\frac{1}{2}$ millions, nor fallen short of $16\frac{1}{2}$ millions, in any one year, from 1802 to 1808, both inclusive, was in 1809 raised to £18,927,833, and in 1810 to £22,541,523. The issues of country bank paper were increased in a still greater proportion; and, as there was no corresponding increase of the business of the country, the discount on bank-notes rose from $2\frac{1}{2}$, in 1808, to from 13 to 16 per cent. in 1809 and 1810.

This depreciation in the value of bank paper being accompanied by a corresponding fall in the exchange, attracted the attention of the public and the legislature. In consequence, the House of Commons appointed, in 1810, a committee to inquire into the subject; and having examined several witnesses, the committee in their report, which is both an able and a celebrated paper, justly ascribed the fall in the value of bank paper, as compared with gold, to its over-issue; and recommended, in the view of correcting the existing evil and of preventing its recurrence, that within two years the bank should be obliged to resume specie payments. But this recommendation not being adopted, the over issue of paper went on increasing. In 1812 it was at an average discount, as compared with bullion, of $20\frac{3}{4}$ per cent.; in 1813, of 23 per cent.; and in 1814, when the maximum of depreciation was attained, it was 25 per cent.

At the period when the restriction on cash payments took place in 1797, it is supposed that there were about 280 country banks in existence; but so rapidly were these establishments multiplied, that they amounted to above 900 in 1813. The price of corn, influenced partly by the depreciation of the currency, and the facility with which discounts were obtained, but more by deficient harvests and the unprecedented difficulties which the war threw in the way of importation, rose to an extraordinary height during the five years ending with 1813. But the harvest of that year being unusually productive, and the intercourse with the continent being then also renewed, prices, influenced by both circumstances, sustained a very heavy fall in the latter part of 1813, and the beginning of 1814. And this fall having ruined a considerable number of farmers, and produced a general want of confidence, such a destruction of provincial paper took place as has rarely been paralleled. In 1814, 1815, and 1816, no fewer than 240 country banks stopped payment; and *eighty-nine* commissions of bankruptcy were issued against these establishments, being at the rate of *one* commission against every *ten and a half* of the total number of banks existing in 1813.

The great reduction that was thus suddenly and violently brought about in the quantity of country bank paper, by extending the field for the circulation of Bank of England paper, raised its value in 1817 nearly to a par with gold. The return to cash payments being thus facilitated, it was fixed, in 1819, by the Act 59 Geo. III.,

c. 78, commonly called Sir Robert Peel's Act, that they should take place in 1823. But to prevent any future over-issue, and at the same time to render the resumption as little burdensome as possible, it was enacted, in pursuance of a plan suggested by Mr. Ricardo, that the bank should be obliged, during the interval from the passing of the Act till the return to specie payments, to pay her notes, if required, in bars of standard bullion of not less than sixty ounces weight. This plan was not, however, acted upon during the period allowed by law; for, a large amount of gold having been accumulated at the bank, the directors preferred recommencing specie payments on the 1st of May 1821.

The fluctuations, referred to above, in the value of paper were exceedingly injurious. From 1809 to 1815, the creditors of every antecedent contract, land-holders whose estates had been let on lease, stockholders and annuitants of every description—all, in short, who could not raise the nominal amount of their claims or incomes proportionally to the fall in the value of money, were to that extent losers. The injustice that would have been done to the creditors of the state and of individuals, who had made their loans in gold, or paper equivalent to gold, by raising the denomination of the coin twenty-five per cent., however gross and palpable, would not have been greater than was actually done them in 1814, by compelling them to receive payment of their just debts in paper depreciated to that extent.

It is true, that after a currency has been for a considerable period depreciated, as much injustice is done by raising, as was previously done by depressing, its value. But there is good reason to doubt whether the depreciation from 1809 to 1815 (for the depreciation of $2\frac{1}{2}$ per cent. during the six preceding years is too inconsiderable to be taken into account) extended over a sufficiently lengthened period to warrant the legislature in departing from the old standard. It is needless, however, to offer any opinion on this rather difficult point, for we have seen that the value of paper was raised in 1816 and 1817 almost to par by accidental circumstances without any interference on the part of government or of the bank. Sir Robert Peel's Act, to which this rise has been ascribed, not being past till 1819, could have nothing to do with what occurred two or three years previously. Its object was twofold, to redeem the pledge given by Parliament to restore the old standard on the return of peace, and to shut the door against any fresh depreciation of paper.

It has sometimes, indeed, been alleged, that the rise in the value of the currency, by reverting to specie payments in 1821, was in reality much greater than was indicated by the previous difference between the values of paper and gold: for, it is maintained that the value of gold was itself raised by that measure. But we doubt whether this opinion have any good foundation. The supply of gold in the commercial world is too vast to allow of its value being sensibly affected by the drain occasioned by the resumption of cash payments in this country. It was probably, in fact, more than compensated by the cessation of hostilities, and the greater use of bills and other substitutes for coin, after the restoration of tranquillity. We are not aware that there is any article that fell in price after the peace of 1815, of which the fall has not been, or may not be, satisfactorily accounted for by changes in the channels of its supply, or in the cost of production, or both. And the rise that has of late years taken place in the price of some articles, is mostly, we believe, to be accounted for in the same way. The decline in the value of gold, in consequence of the increased

Money.

Money. supplies furnished by California and Australia, has hitherto been very trifling indeed. (See Article PRECIOUS METALS.)

SECT. IV.—*Private and Joint-Stock Banks.*

Notices of the issues of private and joint-stock banks.

After the statements already made in regard to the constitution and purposes of these banks, it is unnecessary to enter into further details with respect to them, unless as respects their history and proceedings as issuers of money.

Except during the suspension of cash payments, the issues of the Bank of England have generally been, as they always ought to be, determined by the state of the exchange. But though the greatest, the Bank of England has not been the only issuer of paper in this country. Large amounts have been issued by the provincial banks, and their issues have been but little influenced by the influx or efflux of bullion, but have almost wholly depended on the state of credit and prices in the districts in which they happened to be situated. If their managers supposed that these were good or improving, they rarely hesitated, previously to the new system introduced in 1844, about making additional issues. Hence, when the state of the exchange, and the demand on the Bank of England for bullion, showed that the currency was redundant and ought to be contracted, the efforts of the bank to effect its diminution have been often impeded, and met by a contrary action on the part of the country banks. This was not owing to the ignorance of the latter. Under the supposed circumstances, the country bankers saw, speaking generally, that they ought also to contract; but being a very numerous body, comprising several hundred establishments scattered over all parts of the country, each was impressed with the well-founded conviction, that all that he could do in the way of contraction, would be next to imperceptible; and few thought of attempting anything of the sort, so long as they felt satisfied of the stability of those with whom they dealt. On the contrary, most bankers knew, that had they withdrawn a portion of their notes, some of their competitors would have been eager to embrace the opportunity of filling up the vacuum; and that they would only have lost a portion of their business, without in any degree lessening the amount of paper afloat. Hence, in nineteen out of twenty instances, the country banks went on increasing their issues long after the exchange had been notoriously against the country, and the Bank of England had been striving to pull up.

And not only did they almost universally increase their issues when they ought to have been diminished, but the moment they were compelled to set about their reduction, they ran headlong into the opposite extreme, and unreasonable suspicion took the place of blind unthinking confidence. It is seldom, indeed, that a recoil takes place without its destroying more or fewer of the provincial banks; and provided the others succeed in securing themselves, little attention is usually paid to the interests of those they may have taught to look to them for help. In exemplification of these statements, we shall shortly notice some of the circumstances connected with the destruction of country bank paper in 1792-93, 1813-15, 1825-26, and in 1836-39.

1. Previously to 1759, the Bank of England did not issue any notes for less than £20; but having then commenced the issue of £10 notes, her paper was gradually introduced into a wider circle, and the public became more habituated to its employment in their ordinary transactions. The country banks had not, however, been

so very scrupulous in regard to the magnitude of their notes, which they endeavoured to get into circulation by making them for very small sums. But this being a practice productive of much abuse, was checked in 1775, by Parliament enacting that notes should not be issued for less than £1. In 1777, this minimum limit was further raised to £5, at which point it continued till 1797, when an issue of £1 notes was again authorised.

The distress and embarrassment that grew out of the American war proved exceedingly unfavourable to the formation of country banks, or of any establishments requiring unusual credit or confidence. No sooner, however, had peace been concluded, than everything assumed a new face. Agriculture, commerce, and still more, manufactures, into which Watt and Arkwright's inventions had been lately introduced, immediately began to advance with a rapidity unknown at any former period. In consequence, that confidence which had either been destroyed, or very much weakened by the disastrous events of the war, was fully re-established. The extended transactions of the country required fresh facilities for carrying them on, and these were supplied in the utmost profusion. The number of banks, which in 1784 was certainly under 150, increased so rapidly, that in 1792 they amounted to about 350! In consequence, a banking office was opened in every market-town and in most considerable villages. And such being the case, it is needless, perhaps, to add, that the prudence, capital, and connections of those who set up these establishments were but little attended to. The great object of a large class of traders was to obtain discounts; and the bankers of an inferior description were equally anxious to accommodate them. All sorts of paper were thus forced into circulation, and enjoyed nearly the same degree of esteem. The bankers, and those with whom they dealt, had the fullest confidence in each other. No one seemed to suspect that there was anything hollow or unsound in the system. Credit of every kind was strained to the utmost; and the available funds at the disposal of the bankers were reduced far below the level which the magnitude of their transactions required to render them secure.

The catastrophe which followed, was such as might easily have been foreseen. The currency having become redundant, the exchanges took an unfavourable turn in the early part of 1792. A difficulty of obtaining pecuniary accommodation in London was not long after experienced; and notwithstanding the efforts of the Bank of England to mitigate the pressure, a violent revulsion took place in the latter part of 1792 and the beginning of 1793. The failure of one or two great houses excited a panic which proved fatal to many more. Out of the three hundred and fifty country banks in England and Wales, when this revulsion began, about a hundred were compelled to stop payments, and upwards of fifty were totally destroyed, producing by their fall an extent of misery and bankruptcy till then unknown in the country.

"In the general distress and dismay, every one looked upon his neighbour with caution, if not with suspicion. It was impossible to raise money upon the security of machinery, or shares of canals; for the value of such property seemed to be annihilated in the gloomy apprehension of the sinking state of the country, its commerce and manufactures; and those who had any money, not knowing where they could place it with safety, kept it unemployed and locked up in their coffers. Amid the general calamity, the country banks, which had multiplied greatly beyond the demand of the country for circulating paper currency, and whose eagerness to push their notes into circulation had laid the foundation of their own misfortunes, were among the greatest sufferers, and, con-

Money. Crisis of 1792-93.

Money.

sequently, among the greatest spreaders of ruin and distress among those connected with them; and they were also the chief cause of the drain of cash from the Bank of England, exceeding any demand of the kind for about ten years back. Of these banks above a hundred failed, whereof there were twelve in Yorkshire, seven in Northumberland, seven in Lincolnshire, six in Sussex, five in Lancashire, four in Northamptonshire, four in Somersetshire, &c."¹

Attempts have sometimes been made to show that this crisis was not occasioned by an excess of paper-money having been forced into circulation, but by the agitation caused by the war then on the eve of breaking out. But there do not seem to be any good grounds for this opinion. The unerring symptoms of an overflow of paper—a fall of the exchange, and an efflux of bullion—took place early in 1792, or about twelve months before the breaking out of hostilities. Mr Chalmers states that none of the great houses that failed during this crisis had sustained any damage from the war. The efforts of the country bankers to force their paper into circulation occasioned the redundancy of the currency, and it was on them, and on the country dealers and farmers dependent on them, that the storm principally fell.² It has been already seen, and it is of importance to remark, that the Bank of England had no notes for less than £10, and the country banks for less than £5 in circulation when the crisis of 1792-93 took place.

Crisis of 1814, 1815, and 1816.

2. During the period from 1800 to 1813, the number of country banks increased from about 400 to 922; and in consequence partly of this rapid increase, and partly of the suspension of cash payments at the Bank of England in 1797, and the issue of one-pound notes by that establishment and the country banks, the amount of paper afloat was vastly increased, particularly after 1808, when it sunk to a heavy discount as compared with bullion. Mr Wakefield, whose extensive employment in the management of estates in all parts of the country gave him the most favourable opportunities for acquiring correct information, stated to the agricultural committee of 1821, that "down to the year 1813, there were banks in almost all parts of England, forcing their paper into circulation at an enormous expense to themselves, and in most instances to their own ruin. There were bankers who gave commission, and who sent persons to the markets to take up the notes of other banks; these people were called money-changers, and commission was paid them." (Report, p. 213). And among the various answers to the queries sent by the Board of Agriculture in 1816, to the most intelligent persons in different parts of the country, there is hardly one in which the excessive issue of country-bank paper is not particularly specified as one of the main causes of the unprecedented rise of rents and prices previously to 1814.

We have already seen what was the result of this conduct, and that the extensive destruction of country bank paper at the end of the war, by raising the value of the currency nearly to par, paved the way for the resumption of cash payments at the old standard in 1821.

But notwithstanding the ample experience that had been supplied by the occurrences of 1792-93 and 1814-16, of the mischievous consequences of the issue of paper by the country banks, and of their want of solidity, nothing whatever was done, when provision was made for returning to specie payments, to restrain their issues, or to place them on a better footing. The consequences of such improvidence were not long in manifesting themselves. The prices of corn and other agricultural prod-

ucts, which had been greatly depressed in consequence of abundant harvests, in 1820, 1821, and 1822, rallied in 1823; and the country bankers, true to their invariable practice on similar occasions, immediately began to enlarge their issues. It is unnecessary to inquire into the circumstances which conspired, along with the rise of prices, to promote the extraordinary rage for speculation exhibited in 1824 and 1825. It is sufficient to observe, that in consequence of their operation, confidence was very soon carried to the greatest height. It did not seem to be supposed that any scheme could be hazardous, much less wild or extravagant. The infatuation was such, that even the most considerate persons did not scruple to embark in visionary and absurd projects; while the extreme facility with which discounts were procured upon bills at very long dates, afforded the means of carrying on every sort of undertaking. The most worthless paper was readily negotiated. Many of the country bankers seemed, indeed, to have no object other than to get themselves indebted to the public. And such was the vigour and success of their efforts to force their paper into circulation, that the amount of it afloat in 1825 is estimated to have been nearly fifty per cent. greater than in 1823.

The consequences of this extravagant and unprincipled conduct are well known. The currency having become redundant, the exchanges began to decline in the summer of 1824. The directors of the Bank of England having unwarily entered, in the early part of that year, into an engagement with the government to pay off such holders of four per cent. stock as might dissent from its conversion into a three and a half per cent. stock, were obliged to advance a considerable sum on this account after the depression of the exchange. But despite this circumstance, they might and ought to have taken measures in the latter part of 1824 and the earlier part of 1825, by lessening their issues, to stop the efflux of bullion. But not being sufficiently alive to the urgency of the crisis, the London currency was not materially diminished till September 1825. The recoil, which would have been less severe had the efforts of the bank to prevent the exhaustion of her coffers taken place at an earlier period, was most appalling. The country banks began to give way the moment they experienced a considerably increased difficulty of obtaining accommodation in London, and confidence and credit were immediately at an end. Suspicion having awakened from her trance, distrust had no limits. All classes of depositors made haste to call up the sums they had entrusted to the care of the banks. There was, also, a run upon them for payment of their notes, not in the view of sending the gold as a mercantile adventure to the Continent, but to escape the loss which it became obvious the holders of country paper would have to sustain. *Sauve qui peut* was the universal cry; and the destruction was so sudden and extensive, that in less than six weeks, above seventy banking establishments were swept off, and a vacuum was created in the currency which absorbed from eight to ten millions of additional issues by the Bank of England; at the same time that myriads of those private bills that had previously swelled the amount of the currency, and added to the machinery of speculation, were wholly destroyed.

3. It may be worth while, perhaps, to observe that it has been alleged, in opposition to what is now stated, that the difficulties of the bank in 1825 were not caused by any excess either of her issues or of those of the country banks, but by the too great amount of the capital she had lent; and in proof of this allegation, we are referred to the increase of nearly eight millions in the amount of

Money.

Crisis of 1825 not occasioned by bank lending too much capital.

Crisis of 1825-26.

Money.

securities which the bank held in August 1825 over their amount in August 1822, and to the simultaneous decrease of nearly six and a half millions in the amount of bullion in her coffers.¹ But a little consideration will suffice to show the futility of this statement. It is impossible, indeed, that any mere advance of capital, however great, whether by the bank or any other great association, should affect the state of the currency or the exchanges. It was not the magnitude of the advances, but the mode in which they were made, that brought on the crisis. The bank took no steps, or none of sufficient energy, to reduce the amount of her notes in circulation till long after the exchange had become unfavourable, and bullion was demanded of her for exportation. The accumulation of securities was the necessary result of this radical error. Had the bank made her advances in the shape of produce—in corn, cotton, cloth, or iron—they might have been ten times as great without having the smallest influence over the exchange. But the currency having become redundant in 1824, the notes of the bank were returned upon her for gold, so that her securities were augmented at the same time that her means of dealing with the unfavourable exchange were impaired. It is to be remembered, that the efflux of bullion showed conclusively that, however issued, and whether greater or less than at former periods, the paper afloat was in excess, and that its contraction had become indispensable. And such being the case, it was the bounden duty of the bank, as soon as she felt the drain for gold setting steadily against her, to adopt every means in her power, by raising the rate of interest, selling securities, and otherwise, to reduce her issues, and restore the exchange to par. And had she done this at a sufficiently early period, it is all but certain she would not have lost more than two or three millions of bullion; whereas, by following a different line of conduct, and deferring the adoption of vigorous repressive measures till too late a period, she was drained of about seven millions of bullion, and her safety seriously compromised before she could stop the drain.

It is, therefore, the merest delusion to ascribe the crisis of 1825, or any similar crisis, to the bank advancing too much capital. She did no such thing. What she did was to issue and keep out an excess of notes in the teeth of an unfavourable exchange. It was this that drained her of her bullion; and it would have had precisely the same result had the bank capital been ten times greater than it actually was.²

Measures for establishing joint-stock banks in 1826. Inadequacy of these measures.

4. Notwithstanding nations are proverbially slow and reluctant learners, the events of 1825-26, taken in connection with those of the same sort that had previously occurred, produced a conviction of the necessity of taking some steps to improve the system of country banking in England. But we regret to have to add, that the measures adopted in this view were very far indeed from being effectual to their object. The law of 1708, limiting the number of partners in banking establishments to six, was repealed; and it was enacted, that banks with any number of partners, might be established for the issue of notes anywhere beyond sixty-five miles from

London; and that banks not issuing notes might be established in London itself with any number of partners. The circulation of notes for less than five pounds in England and Wales was at the same time forbidden.

Much benefit was expected, but without much reason, to result from these measures. The suppression of £1 notes was in so far advantageous, that it shut up one of the principal channels by which the inferior class of country bankers got their paper into circulation, and tended, consequently, to secure the labouring classes against loss in the event of their bankruptcy. But the other measure, or that for the establishment of joint-stock banks, proved to be a complete failure. And we have seen in the previous inquiry into the constitution of such banks, that nothing but mischief could be expected to arise from giving them power to issue notes.

Those who supposed that joint-stock banks would be immediately set on foot in all parts of England, were a good deal disappointed with the slowness with which they spread for some years after the Act permitting their establishment was passed. The heavy losses occasioned by the downfall of most of the joint-stock projects set on foot in 1824 and 1825, made all projects of the same kind be looked upon for a considerable period with suspicion, and deterred most persons from embarking in them. But this caution gradually wore off; and the increasing prosperity of the country, and the difficulty of vesting money so as to obtain from it a reasonable return, generated of new a disposition to adventure in hazardous projects. A mania for embarking in speculative schemes acquired considerable strength in 1834, and during 1835 and part of 1836, it raged with a violence but little inferior to that of 1825. It was at first principally directed to railroad projects; but it soon began to embrace all sorts of schemes, and, among others, joint-stock banks, of which an unprecedented number were projected in the course of 1835. The progress of the system was as follows:—

Progress of the joint-stock system.

Banks.	Banks.
In 1826 there were registered..... 6	In 1832 there were registered..... 10
In 1827..... 1	In 1833..... 13
In 1828..... 5	In 1834..... 8
In 1829..... 4	In 1835..... 45
In 1830..... 3	In 1836..... 11
In 1831..... 8	
	Total.....114

In point of fact, however, the number of banks created in 1835 and 1836 was vastly greater than appears from this statement. We believe that, at an average, each of the fifty-six banks established in those years, like those previously established, had from four to five branches; and as these branches transacted all sorts of banking business, and enjoyed the same credit as the parent establishment, from which they were frequently at a great distance, they were, to all intents and purposes, so many new banks; so that, instead of fifty-six, it may safely be affirmed that from about 220 to 280 new joint-stock banks were opened in England and Wales in 1835 and 1836, but mostly in the former!

In January, February, and March 1836, when the rage

Securities of all sorts, 31st August 1822,	£17,290,510
— 31st August 1825,	25,106,030.
Excess of Securities, 31st August 1825, over those held on 31st August 1822,	£7,815,520
Bullion in Bank, 31st August 1822,	£10,097,960.
Do. 31st August 1825,	3,634,320
Diminution of bullion,	£6,463,640

On the 28th February 1826, the bullion in the bank amounted to only £2,459,510.

² Perhaps we may be allowed to observe, that we endeavoured to point out, in an article in the *Scotsman*, published in 1825, what would be the inevitable result of the bank allowing the drain of bullion to run its course, viz., that she would be drained of her last sovereign, and obliged to stop payments; and that she could not avert this result otherwise than by narrowing her issues, and raising the value of the currency. She did this at last, but she ought to have done it nearly twelve months sooner.

for establishing joint-stock banks was at its height, the exchange was either at par, or slightly in our favour, showing that the currency was already up to its level, and that if any considerable additions were made to it, the exchange would be depressed, and a drain for bullion be experienced. But these circumstances, if ever they occurred to the managers of the joint-stock banks, do not seem to have had, and could not in truth be expected to have, any material influence over their proceedings. Their issues, which amounted on the 26th of December 1835 to £2,799,551, amounted on the 25th of June next to £3,588,064, exclusive of the vast mass of additional bills, cheques, and other substitutes for money they had put into circulation. The consequences were such as every man of sense might have foreseen. In April 1836 the exchange became unfavourable, and bullion began to be demanded from the Bank of England. The latter, that she might the better meet the drain, raised the rate of interest in June from four to four and a-half per cent., and this not being enough sufficiently to lessen the pressure on her for discounts, she raised it in August from four and a-half to five per cent. But during the whole of this period the country banks went on increasing their issues. We have seen that, on the 25th of June 1836, their issues were £788,513 greater than they had been on the preceding 26th of December; and notwithstanding the continued drain for bullion, and the increased rate of interest charged by the Bank of England, and the reduction of her issues, the issues of the joint-stock banks increased from £3,588,064 in June, to no less than £4,258,197 on the 31st of December, being an increase of nearly twenty per cent. after the exchange was notoriously against the country; and the most serious consequences were apprehended from the continued drain for bullion.

It may perhaps be supposed that the increased issue of the joint-stock banks would be balanced by a corresponding diminution of the issues of the private banks, and that on the whole the amount of their joint issues might not be increased. This, however, was not the case. Some private banks were abandoned in 1836, and others incorporated with joint-stock banks; and it is farther true, that those which went on managed their affairs with more discretion than their associated competitors. But, from the 26th of September 1835 to the 31st of December 1836, the issues of the private banks were diminished only £159,087, whilst those of the joint stocks were increased during the same period £1,750,160, or more than *ten times* the falling off in the others!

There
should be
only *one*
issuer of
paper-
money.

These statements show the inexpediency of having more than one issuer of paper. Its issue ought in all cases to be governed by the state of the exchange, or rather, as already stated, by the influx and efflux of bullion. But previously to 1844, the provincial banks might go on over-issuing for a lengthened period without being affected by a demand for bullion, or even for Bank of England paper.

In the end, no doubt, an efflux of the former was sure, by rendering money and all sorts of pecuniary accommodation scarce in the metropolis, to affect the country banks as well as the Bank of England; and then the injury to industry, occasioned by the withdrawal of their accustomed accommodations from a great number of individuals, was severe in proportion to the too great liberality

with which they had previously been supplied. This was especially the case in 1836, when the Bank of England, by bolstering up the Northern and Central Bank, averted, though but for a while, the bankruptcy of that establishment, which had no fewer than *forty* branches, and, by doing so, is said to have prevented the occurrence of a panic that might have proved fatal to many other joint-stock and private banks. Still, however, the shock given to industrial undertakings, by the revulsion in the latter part of that year, and in 1837, although unaccompanied by any panic, was very severe. All sorts of commercial speculations were for a while completely paralysed, and there were but few districts in which great numbers of individuals were not thrown out of employment. In Paisley, Birmingham, and most other towns, the distress occasioned by the revulsion was very general and long-continued. And owing to the Bank of England having delayed, in 1838 and the earlier part of 1839, to take efficient measures for the reduction of her issues, despite the unmistakeable evidence of their being redundant, the bullion in her coffers was reduced in September 1839 to £2,406,000; and, but for the efficient assistance obtained from the Bank of France, her stoppage could hardly have been averted.

Money.

SECT. V.—*Act of 1844. Objections to and Defence of that Act. Suspensions of in 1847 and 1857.*

This perilous experience having again forcibly attracted the public attention to the state of the banking system, 1844. Sir Robert Peel was induced to attempt its improvement. The clause in the Act 3 and 4 Will. IV. c. 98, which renewed the Bank Charter in 1833, gave Parliament power to revise or cancel it in 1845, and thus afforded a legitimate opportunity for the introduction of the new system. It was indispensable, in attempting to obviate the defects inherent in our currency, to proceed cautiously, to respect, in as far as possible, existing interests, and to avoid taking any step that might excite the fears or suspicions of the public; the grand difficulty being to reconcile such a course with the adoption of any plan that would obviate in any considerable degree the defects complained of. Happily this difficult problem was satisfactorily solved. The measures which Sir Robert Peel introduced and carried through Parliament in 1844 and 1845, for the improvement of our banking system, were so skilfully contrived as to provoke little opposition, at the same time that they effected most important and highly beneficial changes.

The measures in question consisted of the Act 7 and 8 Vict. c. 32, which refers to the Bank of England, and the English country banks; and the Acts 8 and 9 Vict. c. 38, 37, referring to the banks of Scotland and Ireland. These statutes were intended to obviate the chances of over-issue, and of sudden fluctuations in the quantity and value of money, by limiting the power to issue notes payable on demand, and by making the amount of such notes in circulation vary with the amount of bullion in the possession of the issuers. In dealing with the Bank of England, Sir Robert Peel adopted the proposal previously made by Lord Overstone,¹ for effecting a complete separation between the issuing and banking departments of that establishment, and giving the directors full liberty to manage the latter at discretion, while they should have no power whatever over the other.²

¹ In tracts published in 1837 and 1840, and in his evidence before a committee of the House of Commons in the latter year.

² It is right to state, that except in so far as he no doubt profited by the suggestion referred to, the measures adopted by Sir Robert Peel in 1844 and 1845 were entirely his own. And they will continue to be enduring monuments of the depth and clearness of his views, and of his administrative ability. This is a point in regard to which the evidence of Lord Overstone is quite decisive; and it is difficult to say, whether that evidence redounds more to his lordship's credit, or to that of the illustrious statesman whose claims to the gratitude of the country as the founder of a sound system of currency, he has so generously and successfully vindicated. "I," said Lord Overstone

Money.

Principle
on which
Act of
1844 was
founded.

The notes of the Bank of England in circulation for some years previously to 1844 rarely amounted to twenty or sunk so low as sixteen millions. And such being the case, Sir Robert Peel was justified in assuming that the circulation of the bank could not, in any ordinary condition of society, or under any mere commercial vicissitudes, be reduced below fourteen millions. And the Act of 1844 allows the bank to issue this amount upon securities, of which the £11,015,100 she has lent to the public is the most important item. Inasmuch, however, as the issues of the provincial banks were at the same time limited in their amount, and confined to certain existing banks, it was further provided, in the event of any of these banks ceasing to issue notes, that the Bank of England might be empowered, by order in council, to issue, upon securities, two-thirds, and no more, of the notes which such banks had been authorised to issue. Under this condition, the total secured issue of the bank has (1857) been increased from £14,000,000 to £14,475,000. *But for every other note which the issue department may at any time issue over and above the maximum amount (£14,475,000) issued on securities, an equal amount of coin or bullion must be paid into its coffers.* And hence, under this system, the notes of the Bank of England are rendered really and truly equivalent to gold, while their immediate conversion into that metal no longer depends, as it previously did, on the good faith, the skill, or the prudence of the directors. And these important results have been attained without imposing any burden of which any one has any right to complain. Our currency rests on the fundamental principle, that all debts above forty shillings shall be paid in gold. But individuals and associations, including the banking or commercial department of the bank, have the option, if they prefer it, to exchange gold for bank notes, and to make use of the latter in their dealings with the public. Hence, if A or B goes to the issuers of paper, and gets 100 or 500 notes from them in exchange for an equivalent amount of gold, it is his own convenience he has exclusively in view. He was at full liberty to use gold, but he preferred exchanging it for notes because he could employ the latter more advantageously. This is the way in which paper is issued under the Act of 1844; and such being the case, it is contradictory to say that it is productive either of hardship or inconvenience.

It has sometimes been proposed to increase the issue upon securities from fourteen to fifteen or sixteen millions. But though a measure of this sort would in nowise affect the amount of the currency, it would in some degree, perhaps, diminish the security for its conversion in periods of difficulty; and the advantage that would result from setting free one or two millions of bullion is too trifling to be gained by exposure to such a contingency.

Proposal to issue in-part of our subject, shortly to observe, that it was suggested to the late Committee on Banks (1857), that the currency might be improved by issuing some fourteen or twenty millions of inconvertible notes. (*Min. of Evidence*, pp. 441-449). The deserts of this proposal may be easily appreciated; and it would not have been worth

Proposal
to issue in-
part of our
subject, shortly
to observe,

notice had it not been one of the few practical measures recommended by the opponents of the Act of 1844. It is plain that inconvertible notes, supposing them to be issued in moderate quantities, or to the extent of fourteen millions or thereby, would not serve all the purposes, nor be of the same value as those that are convertible; and if they circulated, it would only be at a fluctuating rate of discount, as compared with other notes and coins. And while the greatest confusion and disorder would thus unavoidably result from their issue, nothing whatever would be gained by it beyond what is gained by the present system. All notes are now payable in gold on demand; but as it is abundantly certain that fourteen millions of notes will be at all times retained in the pockets of the public, that amount is allowed to be issued on securities. It is obvious, therefore, that while we avoid its endless inconveniences, we should realise nothing by the issue of fourteen millions of inconvertible notes, beyond what is realised under the Act of 1844. These, however, though sufficiently conclusive, are inferior considerations. If once we begin to issue such notes, it is impossible to say where we shall be allowed to stop. The principles, if so we may call the crude and contradictory assertions of the proposers of this notable scheme, would justify an issue not merely of fourteen or twenty, but of forty or fifty millions, or any greater sum. But it is not conceivable that it should meet with any countenance from any portion of the public, much less that it should be adopted. If it were, it requires little prescience to foresee that its results would be alike speedy and disastrous. What has repeatedly happened under the like circumstances would no doubt happen again. Gold would be driven from the country; all contracts would be upset, and we should be fortunate indeed if we escaped a national bankruptcy and revolution. If we take to dealing in assignats, we need not hope to escape its inevitable results.

Money.

But, dismissing such crotchets, it is alleged that the new Act of 1844 does system is injurious by shackling the bank in the use of her credit. But it must be clear on the least reflection that it does nothing of the sort. It merely prevents the bank from issuing substitutes for money which do not represent money. It does not absorb or lock up a single sixpence worth of her capital; nor does it interfere in any manner of way with her employment either of it, or of her credit. The gold in the issue-department of the bank was not purchased by her, and does not belong to her. She is its keeper, but not its owner. It belongs to the public, or to the holders of bank notes, who deposited it in the bank in exchange for notes, with and under the express stipulation, that on paying the latter into the bank, they should receive back their gold. Any interference with these deposits would be an interference with property held in pledge for others, that is, it would be an act precisely of the same kind with that which deservedly subjected Strahan, Paul, and Co. to transportation for fourteen years. The authority of Mr. Sheffield Neave, the present governor of the bank, may be quoted in corroboration of this statement:—"The issue department is put out of our hands altogether. We are

1844 does
nor shackle
the bank in
using her
credit.

"had no connection, political or social, with Sir Robert Peel. I never exchanged one word upon the subject of this Act with Sir Robert Peel in my life, neither directly nor indirectly. I knew nothing whatever of the provisions of this Act until they were laid before the public, and I am happy to state that, because I believe that what little weight may attach to my unbiassed conviction of the high merits of this Act, and the service which it has rendered to the public, may be diminished by the impression that I have something of personal vanity in this matter. I have no feeling whatever of the kind. The Act is entirely, so far as I know, the act of Sir Robert Peel, and the immortal gratitude of the country is due to him for the service rendered to it by the passing of that Act. He has never been properly appreciated, but year by year the character of that statesman upon this subject will be appreciated. By the Act of 1819, Sir Robert Peel placed the monetary system of the country upon an honest foundation, and he was exposed to great obloquy for having so done. By the Act of 1844, he has obtained ample and sufficient security that that honest foundation of our monetary system shall be effectually and permanently maintained. And no description can be written on his statue so honourable as that he restored our money to its just value in 1819, and secured for us the means of maintaining that just value in 1844. Honour be to his name."—(*Min. of Evidence*, p. 178, *Committee of 1857*.)

Money.

mere trustees under the Act of Parliament, to see that those securities are placed there and kept up to that amount; and in no case can any creditor of the bank touch that which is reserved for a note-holder. We are in that respect merely ministrative; we are trustees to hold that amount in the issue-department, and our banking department has a totally separate function, which has no relation whatever to the issue-department."—(*Min. of Evidence*, 1857, p. 99.)

But though she may not lay violent hands on the property of the public, the bank, it is obvious, has at this moment the same absolute command over her entire capital and credit, that she would have were the Act of 1844 non-existent. In her banking capacity she is free from all restraint, and is in precisely the same situation as other banking or mercantile establishments. She may lend or not lend as she pleases, and may lay down such conditions as she pleases in regard to the interest and the terms of her loans and discounts. In short, she may do whatever she likes with her own. But farther she is not permitted to go. She may not substitute shadows for realities. She cannot, whether to assist others, or to relieve herself from embarrassment, issue a single note except upon a deposit of bullion. But this rule does operate on herself only. It applies to all individuals and associations. And to relax it in any degree would be—disguise it as you will—to authorise an issue of fictitious or spurious paper, and consequently to vitiate the currency and to abuse credit in the way that is sure to be in the end the most disastrous.

This statement shows the groundless nature of the charge which is often made against the Act of 1844, that under its operation the bank runs the risk of being brought to a stop, though she may have some five, six, or even eight millions bullion in her coffers. For it is plain that two things are confounded in this charge, which are quite distinct, and have no necessary connection with each other, viz., the proceedings of the bank in her capacity of issuer of notes, and her proceedings in her capacity of a banking company. In her former capacity it is all but impossible that she should be brought to a stop; and if such a thing should happen, there would not then be an ounce of bullion in her coffers. It is not, however, impossible, nor even very improbable, that the bank should be brought, in her mercantile capacity, into difficulties, while there may be a large amount of bullion in the issue-department. But, though such should be the case, is that any reason why she should be permitted to draw on funds that do belong to her, and over which she has no control? Strahan, Paul, and Co. were in difficulties when they sold the bonds and other securities intrusted to their care. And supposing the bank were in difficulties, is she to be allowed to right herself by setting aside the principle of *meum* and *tuum*, and seizing on what belongs to others? Her directors would be the first to repudiate such a doctrine. It may be popular among the founders and managers of the Royal British Bank, and their associates and admirers here and elsewhere, but it will be contemptuously rejected by all men who have any sense of honour, or regard for character.

Act of 1844 has not increased fluctuations of interest.

We have already seen that the facility with which fictitious paper might be issued previously to 1844 was, on many occasions, greatly abused, and that by giving a powerful stimulus to speculation and over-trading, it promoted in no ordinary degree, even when it did not originate, those periods of artificial prosperity that never fail to terminate in bankruptcy and ruin. But though such stimulus can no longer be applied, it is alleged that

the Act of 1844 has increased industrial vicissitudes by increasing the number and intensity of fluctuations in the rate of interest. But this charge is no better founded than the others. Previously to the modification of the usury laws in 1839, the bank could not charge more for loans than 5 per cent.; and for some considerable period after the restriction had been removed, the directors, influenced in part at least by their accustomed habit, permitted on several occasions the bank to be involved in difficulties which might have been averted by their sooner raising the rate of discount. But everybody who knows anything of the matter, must know that the measures of the bank do not determine the general rate of interest. She of course fixes the rate at which she will lend; but her rate is one thing, and the market rate another. Generally, she regulates her proceedings by the fluctuations in the latter. If, on the one hand, the rate of interest fixed by the bank were above the market rate, none but fools, or persons in desperate circumstances, would resort to her for discounts; while, on the other, if it were below that rate, the demands upon her would be so very great that her means would be speedily exhausted. Whether, therefore, there have been more or fewer fluctuations in the rate of interest since 1844, than in any previous period of equal duration, it is difficult to say, and the fact, were it ascertained, would be wholly immaterial to this question. Fluctuations in the market rate of interest seldom depend, in any degree, and never to any considerable extent, on the proceedings of those whose paper, like that of the bank, is equivalent to, and may be immediately converted into, gold. They are brought about by widely different means; by fluctuations in the rate of profit depending on the negotiation of loans; the greater or less demand for capital caused by the opening of new and the shutting up of old commercial channels; the increased efficiency of industry; the undertaking of new projects; and so forth. Fluctuations originating in such widely different causes, must necessarily be of frequent though uncertain occurrence. There can, however, be no manner of doubt, as has been already seen, that their frequency and violence are uniformly and greatly increased by the revulsions consequent on over-issues of paper. At this very time (November 1857) in the United States, which are sufferers from a recoil of this sort, the rate of discount on first class bills varies from 20 to 30 and 40 per cent., while inferior paper cannot be negotiated on any terms. The Act of 1844 has made such ruinous fluctuations, or anything approaching to them, impossible in this country, and on that ground alone, were there none else, it is entitled to the support of all save the merest gamblers.

While, however, the commercial vicissitudes which take place in this country are trifling compared with those that take place in the United States, they are also much less severe than those which occurred prior to the Act of 1844. But no one ever said or supposed that that Act, or that any other possible Act, would free us entirely from such vicissitudes. Its object was to insure at all times the equality of gold and paper, and to redress an adverse exchange. But though these great ends be completely effected, we are still necessarily left to contend with such evils as may result from the revulsions and contingencies inseparable from our enormously extended credit and commercial systems. Speculation, and the miscalculation inseparable therefrom, will continue; credit will be given to those from whom it should be withheld; bad harvests will no doubt recur; American and other extensive importers of our produce, will sometimes fail to make good their engagements; great corporations will sometimes be mismanaged; and mistaken views will sometimes

Money.

Money. prevail amongst the public. And the distress occasioned by the occurrence of these and other contingencies, may be severe, long continued, and widely diffused. But while, on the one hand, the bubble of unnatural prosperity is no longer inflated, as was formerly the case to a vast extent, by issues of spurious paper, so, on the other, the suffering and distress caused by the subsequent revulsion, are no longer inflamed and aggravated by their withdrawal or destruction.

The truth is, that no commercial crisis has been, or can be, averted by making issues of fictitious paper. On the contrary, by improperly bolstering up parties not entitled to credit, and by preventing that timely contraction of the currency which is necessary to correct an adverse exchange, they invariably tend to increase the mischief they are meant to alleviate. To tamper with the currency, except under the exigency of internal discredit or of a panic, is a totally inexcusable proceeding. Having adopted gold for the standard of our money, it is our bounden duty to keep such paper as is substituted for gold, on a par with it. Indeed it would be quite as correct to say that a commercial crisis may be mitigated by a change in our measures of length, capacity, or weight, as by a change in our measure of value.

Currency not limited by Act of 1844.

It is further objected to the Act of 1844, that it "limits the currency;" that it makes no provision for the increasing demands of the public; and confines us, in 1857, when the exports will probably exceed 120 millions, to the same amount of money as in 1844, when the exports did not exceed 58½ millions. But though this statement has been made by parties who ought to have known better, the reader can hardly require to be told that it is completely destitute of foundation. The £14,000,000 issued on securities, is the only thing that is limited in the Act; every thing else varies with the varying condition and circumstances of the country, including the means by which the use of money may be economised. In the week ended the 29th of August 1857, the issue department of the bank had issued notes to the amount of £25,323,965, being no fewer than £11,323,965 over and above the amount authorised to be issued on securities. And if the country had really required a larger supply of money, that is, if more coins, or paper equivalent to coins, could have been absorbed into the circulation without rendering the currency redundant, and depressing the exchange, the additional quantity would have been forthwith supplied. For, under such circumstances, merchants, bankers, and money-dealers, would have realised a certain and immediate profit by carrying bullion to the mint or the bank, that they might obtain coins, or notes, or both, with which to increase the currency. It is one of the chief merits of the Act of 1844, that, under its agency, the supply of money is not to any extent or in any degree regulated or influenced by the proceedings of the bank, or the government. They have nothing to do in the matter, unless it be to coin the bullion which individuals or firms carry to the mint for that purpose, and to exchange, when called upon, notes for coins, and coins for notes. The supply of money, like that of all non-monopolised articles, is wholly dependent upon, and is determined by the free action of the public. It would, indeed, be quite as true to say, that the Act of 1844 limits the amount of corn, of cloth, or of iron produced in the country, as that it limits the amount of money. It maintains the value of the notes issued by the bank on a level with the coins for which they are substitutes; but beyond that its effect is *nil*. It has nothing whatever to do with the greater or less amount of the currency. That depends entirely on the estimate formed by the public of its excess or deficiency, an estimate

VOL. XV.

which, when wrong, is sure to be corrected by the Money. exchange.

We may add, that no inference can ever be safely drawn from the number of notes or coins, or both, afloat in a country, as to whether its currency be, or be not, in excess. That is to be learned by the state of the exchange, or by the influx and efflux of bullion. If the imports of bullion exceed the exports, it shows that the currency is in some degree deficient; while, if the exports exceed the imports, it shows that the currency is in excess, and that no additions can be made to it without farther depressing the exchange and increasing the drain of bullion. When the imports and exports of bullion are about equal, then of course the currency is at about its proper level. These are the only criteria by which anything can ever be correctly inferred, in regard to the deficiency or excess of currency. Its absolute amount affords hardly even a basis for conjecture. When there is little speculation or excitement, an issue of 25 or 27 millions bank notes may be in excess; while, at another time, and with a different state of trade and speculation, an issue of 35 or 37 millions of notes may not be enough. Except in periods of internal commotion, or when we are disturbed by alarms of invasion, the state of the exchange is the only, as it is the infallible, test of the sufficiency and insufficiency of the currency.

We may farther state, that those who are in the habit of complaining of the limitation of the currency by the Act of 1844, almost uniformly underrate its amount. We have already seen that, in the week ending the 29th August 1857, the notes issued by the issue department of the bank amounted to £25,323,965, of which £5,999,790 were in the banking department of the bank, leaving a balance of £19,324,175 in the hands of the general public; and this latter sum is, we are told, the real amount of the issues. But this is falling into the rather serious blunder of mistaking a part for the whole. The notes in the banking department of the bank make not only a part, but a most important and active part, of the currency of the country. They constitute the means, along with the bullion in the same department, with which the bank carries on her banking business, and are as evidently a portion of the currency as the notes in the tills of private bankers and the pockets of individuals. The notes in the banking department of the bank must therefore never be omitted in estimating the amount of notes in circulation. The latter, and the notes out of the issue department, are identical; and, in a general point of view, it matters not a straw whether they are in the hands of the banking department of the bank or of individuals.

Notes in the banking department of the bank an important part of the currency.

We have seen that bills of exchange, about which so much is said, though they serve some of the purposes of money, are not money. But whether the amount of them in circulation be great or small, and whether they be drawn at long or short dates, though highly important in other respects, has no reference to, or bearing upon, this question. When from any cause, whether from an excess in the amount of bills, or notes afloat, the currency becomes redundant, the exchange is depressed, and notes are sent to the issue department of the bank to be exchanged for gold, which is forthwith exported. And it is by the immediate action of the adverse exchange upon notes, and the consequent influence of the contraction of the latter upon bills, that the amount of the currency is lessened, its value raised, and the exchange brought to par. At such periods there is usually more or less of mercantile pressure, and a greater demand for discounts and pecuniary accommodation. This leads to a rise in the rate of interest; but no change in this rate has any

Mercantile pressure not aggravated by Act of 1844.

Money. influence over the currency, except in so far as its rise may diminish, and its fall may increase, the demands upon the bank for loans. A system of this sort effectually prevents any great excess of bills from ever getting into the market; and thus checks, *in limine*, what would otherwise be the most copious source of wild speculation, overtrading and bankruptcy.

The operation of the present system during the late war with Russia, was in all respects eminently satisfactory. It stood in the way of no legitimate transaction, of no fair exercise of the credit, either of the state, or of individuals. But as it was a powerful obstacle to the creation of artificial credit, it was eminently unpopular with those who supposed they would profit by such abuse. It is doubtful, indeed, had the war continued for two or three years longer, whether government might not have been compelled to resort to an inconvertible paper, and consequently to place the property of the public, and of every individual, at the mercy of its issuers!

It is, therefore, wholly untrue to say that the Act of 1844 aggravates the severity of any mercantile pressure that may occur. Its practical effect is to do what other Acts professed but failed to do, that is, to make paper and gold precisely of the same value, and to insure the immediate conversion of the former into the latter. This is what the Act of 1844 really does. And to say that this aggravates either pressure or distress, is equivalent to saying that it would be aggravated by employing a purely metallic currency, or by maintaining a practically invariable measure of value, which is absurd. A gold currency interposes no obstacle to the free transfer of capital from one party to another, and has in truth no influence of any sort over its distribution, its employment, or the rate of profit. How, then, can it either occasion distress, or add to its pressure. It is not difficult to discover, in the stimulus given to emigration and industry by the discovery of the Californian and Australian gold fields, in the destruction of capital occasioned by the late war, in the hoarding now going on in India, China, and other countries, in the improvement of industry and the extension of commerce, and in the various schemes afloat, the causes of the present high rate of interest. But whatever they may be, the equality of gold and paper in England cannot be one of them. Neither can it be said to be occasioned by a scarcity of gold, for we have exported it to all parts of the continent; and interest is more than three times as high in California, and more than twice as high in Australia, in both of which gold is comparatively cheap, as in the United Kingdom.

It is quite true, that if the check on the issue of paper were less cogent than at present (1857), parties might, perhaps, be tempted to lend it at less than 6 or 5, or even 4 per cent. But, down to a very late period, the currency, as shown by the exportation of gold, was really redundant; and hence it is obvious, that the issues now referred to, supposing they had been made, would, by making it still more redundant, have depressed the exchange to a still greater extent, and proportionally increased the drain for gold. Every device of this sort, that is, every attempt to obviate a foreign drain by encroaching on the integrity of the currency, is sure to lead to mischief. It may, like drams administered to a person with a broken-down constitution, have a momentary effect, but

the collapse is inevitable, and is sure to be ruinous in proportion to the previous abuse of the stimulant. **Money.**

It may be said, perhaps—for there is no end of apologies for whatever is vicious—that if the issue of notes were in the hands of government, the entire profit accruing thereon would belong to the public. But supposing such to be the case, the difference between that profit, and that which is or may be realized under the present system, would either be nothing at all, or so inconsiderable as to be wholly unworthy of attention. It will be afterwards seen that at this moment the public receives by far the greater part of the profit made by the bank on the fixed issue of £14,000,000, and if it be deemed expedient, that part may be still further increased, or turned into the lion's share. Assuming, therefore, for a moment, that the power to issue notes is vested in government commissioners, it is not pretended that these notes are to be legal tender. Nothing so monstrous as that could be thought of, or at all events, durst be proposed. The notes issued by the commissioners, like those issued by the bank, must be paid on demand. But to do this, a stock of bullion must be provided; and unless the plan now followed were adopted, and all issues above the amount of £14,000,000, or thereby, were made upon deposits of bullion, the public would not have that perfect security which is given them by the present system, and which is worth more than ten times all the profits arising out of the fixed issue. Even under the old system, or that which existed previously to 1844, the rule of the bank was to keep a stock of bullion on hand equal to a third part of her issues. But this rule was not, and in truth could not, be acted upon. It is plain, however, had it been *bona fide* carried out, that the profits on the issue of notes would not have been materially, if at all different, from what they are at this moment. Nothing, therefore, can be more completely futile than the talk about the large profits that would accrue to the public by vesting the power to issue notes in commissioners appointed by government. With the same security as at present for the conversion of the notes into coin, nothing would be gained by such appointment; and if, as would most likely be the case, it lessened the security referred to, and added to the chances of over-issue and mismanagement, the injury to the public hence resulting might be enormous. We, therefore, are disposed to believe, that of the various proposals in regard to the currency, that which proposes to vest the issue of notes in the hands of government commissioners, is one of the most objectionable. The chances are ten to one that they would act as directed by the government of the day; and this, at all events, would be popularly assumed to be the case. Supposing, however, that they did nothing of the sort, but were perfectly independent, still it is obvious, that whatever they did more or less than is done at present, would be mischievous. And such being the case, it is not easy to see what advantage would be gained by their appointment; while it would have the serious disadvantage of making government directly responsible, in the public estimation, for whatever inconvenience might at any time be supposed to result from the limitation of the currency.

Another class of opponents to the Act of 1844, though

Proposal for vesting the issue of notes in the hands of government commissioners.

¹ Among the many charges which have been made against the Act of 1844, one of the most extraordinary, if not the most absurd is, that it doubles the intensity of all demands for bullion on the bank, or converts a demand for one million into a demand for two! A million of notes are got, it is said, from the banking reserve of the bank, and these being sent to the issue department, are exchanged for gold, so that the bank has sustained a loss of two millions. It is singular that so obvious a fallacy should have been put forward. The gold in the issue department does not belong to the bank, but to the note-holders, so that she sustains neither loss nor injury by its being withdrawn. In this case, and in all cases of the sort, the notes in circulation are reduced a million, and their equivalent in gold is exported.

Money.
Proposal to have notes issued by the mint on deposits of gold.

but a small minority, take a different ground from most of those already noticed, and contend not that the Act is too strict, but that it is not strict enough. According to their view of the matter, no notes should be issued on securities. And they propose, conformably to their theory, that the issue of notes should be transferred from the bank to the mint, and that none should be issued except upon the deposit of a corresponding amount of bullion. This project, however, were it adopted, would not be productive of any advantage of any kind whatever, while it would abstract more than fourteen millions of capital from useful purposes. There is not, as already seen, the smallest chance that, under ordinary circumstances, or in the absence of internal commotion or panic, the issue of bank-notes will ever be reduced so low as £14,000,000; and it is therefore quite enough for every purpose of security, that the notes above that limit should be issued on deposits of bullion. How invaluable soever, it would be absurd to make greater sacrifices in favour of security than what are sufficient to obtain it in its most perfect state; and these are fully realized by the Act as it now stands.

It is argued, indeed, by those who have brought forward this scheme, that it would greatly improve the conduct of the bank, and that there would henceforth be fewer fluctuations in the rate of interest, and so forth. But every one must see that those who make such statements confound the proceedings of the bank as issuer of notes, with her proceedings as a great banking association. In truth and reality, however, the former have no connection with the latter; and are conducted precisely as they would be were the suggestion now under consideration to be adopted. In her proceedings as a great banking company, the bank is necessarily affected by all those circumstances which affect the trade and industry of the empire and the world, the state of the exchange, the demand for discounts and loans, and so forth. She must act accordingly, and adapt her measures to the varying wants and exigencies of society. But it is indifferent to the banking department of the bank, whether the notes which are used by it are obtained by carrying an equivalent amount of gold to the issue department, or to any other place. And such being the case, it is clear that the proposed plan, were it adopted, would obviate none of the inconveniences, if such there be, that attach to the present system, while it would introduce others which at present have no existence. For it would occasion a waste of the national resources by unnecessarily locking up fourteen millions of gold; and it would place the issue of paper, where it never ought to be placed, in the hands of government officers. But it is needless to enlarge further on a scheme which is sure to be repudiated by all parties.

Act of 1844 restrains country issues.

The objections to the Act of 1844 are so various and so opposite that they are not easily recollected. Sometimes we are told that it is inconsistent with itself and incomplete, and that it deals stringently with the Bank of England, while it hardly interferes with the country banks. But this is an unfair representation. In dealing with the country banks the Act may not have gone quite so far as it was desirable it should have gone, or as Sir Robert Peel wished it to go; but it notwithstanding effected, even in that respect, a very great improvement, and really left but little to be wished for.

To prevent future over-issues of country paper, it was enacted, that from and after the passing of the Act, no new bank for the issue of notes should be established in any part of the United Kingdom. And it was farther

enacted, that the *maximum* issue of notes by the existing country banks should, in future, be limited to the average amount which they had respectively in circulation during the twelve weeks preceding the 27th April 1844;¹ and various penalties are imposed on those whose issues exceed that fixed amount. It was then, also, ordered that the names of the partners, in joint-stock and other banks, should be periodically published.

These are most important regulations. No doubt it would have been better had provincial issues been entirely suppressed, and Bank of England notes been made the only legal substitute for coins. But in matters of legislation what is practicable is of quite as much importance as what is absolutely just and proper. Sir Robert Peel knew what he could carry through Parliament. Had he attempted more he would not only have failed of his object, but would, most likely, have endangered the success of the other and far more important portion of his measure which related to the Bank of England.

Under the operation of the Act of 1844 the extinction of the country issues is being gradually effected, partly by some of the issuing banks finding it to be for their advantage to use notes of the Bank of England instead of their own, and partly by the winding up of some concerns and the bankruptcy of others. But, owing to the limitation of the issues, comparatively little inconvenience has resulted to the public from the latter circumstance.

On the whole, therefore, there does not appear to be much ground on which to object to the existing arrangements in regard to the country banks. Though not theoretically perfect, their practical deficiencies are unimportant. To attempt to obviate them might imperil other and more important arrangements. And we incline to think that the notion that such would be the case has had not a little to do in making them be pressed on the attention of the public.

But it is said, "that even the best system cannot always be carried to an extreme. The Act of 1844 has had to be suspended in 1847, and again in 1857; and machinery for its relaxation in periods of difficulty should be introduced into it!"

Suspensions of 1847 and 1857.

We beg, however, to express our dissent from this doctrine. It would be easy to show that the embarrassment of the banking department of the bank in 1847 was mainly a consequence of the injudicious proceedings of the directors; and it is to be hoped that the experience they acquired on that occasion may not be forgotten. But in whatever way the crisis may have originated, there can be no question that the suspension of the Act in 1847 was a measure of doubtful policy. The exchanges had already become favourable, and it was the prevalent opinion in very well-informed quarters, that the panic which had begun to show itself would speedily have disappeared without the intervention of government. It should never be forgotten that, apart from internal panics, the time when the Act is said to be working harshly and oppressively, is the very time when it is most for the public advantage that it should be honestly carried out.

That such is the case is admitted by the highest authorities, and among others by Mr Hubbard, late governor of the bank. "As limitation of credit paper is," says he, "of the very essence of the Act of 1844, and as limitation operates sensibly only under circumstances of pressure, it is obvious that to evade its stringency because a pressure is felt, is simply to stultify the Act; while again, to admit a provision for extending the

¹ This condition applies only to banks in England and Wales. The issues of those in Scotland and Ireland are limited to the average amount of those in circulation during the twelve months ending the 1st of May 1845. See *post*.

Money.

credit issue in the event of difficulties arising from any possible or prospective contingency, would be to encourage overtrading, and foster in the banking community an unwarrantable dependence upon the Bank of England, while they make immoderate engagements, and neglect to maintain an adequate reserve for their own protection."¹

In regard to the late suspension of the Act, we are, perhaps, too near the occurrence to be able to judge dispassionately of its policy. Owing, in no inconsiderable degree, to the prudence with which the business of the bank has been conducted of late years, there has not been, until very recently, any material amount of mercantile distress. Credit, indeed, is apt at all times to be incautiously and improperly given, and there is uniformly a good deal of overtrading and unwarranted expenditure. But except when a revulsion, or something else occurs to deprive parties who are overtrading of their accustomed accommodations, a system that is rotten at the heart may wear an imposing appearance, and seem to be possessed of that solidity of which it is wholly destitute. When, however, the hollowness of such a state of things is laid bare, it would be a gross abuse to attempt by forced measures to bolster up a parcel of mismanaged, bankrupt or ricketty concerns. Such a proceeding is unjust to all those parties who have conducted their businesses soberly and cautiously; and it tempts others to engage in reckless courses, from believing that government will, in the event of their speculations breaking down and being on a sufficiently large scale, volunteer to keep them on their legs.

This last is a most important consideration. In business matters, as in every thing else, individuals should be taught to rely exclusively on themselves. Those who rely on others are necessarily less industrious, cautious, and provident, than if they had no such dependence. They believe that, when the evil days come, they will be helped out of their difficulties; and they therefore make no provision against them, or none that is adequate. It is not easy to estimate the pernicious influence of the statements that are so frequently put forth, of this, that, and the other house, being in difficulties, and of their having obtained large advances from the bank, or other great associations. In nine cases out of ten these difficulties might have been avoided; and had the parties not been pretty well assured that assistance would be granted, they would not have needed it. They would have confined their engagements, and still more their expenditure, within reasonable limits; and their solvency or bankruptcy would not have depended on the judgment or caprice of any set of men. All applications for relief should be rigorously scrutinised; and those best qualified to form a just opinion on such subjects, are of opinion, that there are but few cases in which it is for the public advantage that they should be complied with. "An avowed system," said the most distinguished merchant of his day, "of leaving things to take their own course, and of not listening to the interested solicitations of one class or another for relief, whenever the imprudence of speculation has occasioned losses, will, sooner than any artificial remedy, reproduce that equilibrium of demand and supply which the ardour of gain will frequently derange, but which the same cause will, when let alone, as infallibly restore."²

But, however important, even these principles are not to be carried out at all hazards. The *salus publica* is the first consideration, and to it all others must give way. And if, at any time, it can be shown that that grand principle would be compromised by abiding by the Act of 1844, or by any other Act, then undoubtedly it ought to be suspended. But the necessity for interference must be clearly made out.

Nec deus intersit, nisi dignus vindice nodus
Inciderit.

The late revulsion, which grew out of the stoppage of the American banks, is said to be an instance of the kind now referred to. The real value of the exports from this country to the United States amounted in 1856 to £21,476,000, of which a large portion was unpaid when the banks stopped payments; and a further and very large sum was due to us on account of dividends on state, railway and canal stocks, and so forth, held by parties in England. The sudden cessation of so large an amount of payments could not fail to occasion a good deal of distress among the merchants and others dealing with America. And it was among this class, or those intimately connected with it, that the greatest overtrading and abuse of credit had taken place. Some firms in Glasgow, which had been notoriously overtrading for a number of years, were the first to give way. And their failure being on a very large scale, the banks³ by which they had been principally supported became the objects of suspicion. And from suspicion to distrust there is but a step. Notwithstanding the numbers and wealth of the shareholders responsible for the banks in question, they were subjected to a run on the part of the inferior class of note-holders and depositors, and their resources being either anticipated or locked up, they were obliged to suspend payments. And had they only failed, none could have regretted the result. On the contrary, it would have been nothing more than they deserved, for they had for a lengthened period grossly abused the ample resources at their command, and resorted to the most questionable means to bolster up the speculators with whom they had become identified. But the mischief is, that the disastrous effects of such proceedings cannot be confined to the guilty parties. A fire originating in a pig-stye may destroy a palace. The suspension of the offending banks, by generating uneasy feelings and suspicions in the public mind, led to a run on some of the other banks. And to provide for their own safety these establishments immediately began to sell securities, and to adopt other means, by which to obtain supplies of gold. Large amounts of it were in consequence carried to Scotland. And, in addition to the demand for gold, that for discounts, notwithstanding the high rate of ten per cent. charged by the bank, continued undiminished, so that the reserve in her possession was reduced on the 11th of November to £1,462,153; and it was the general belief, that this inadequate reserve would be forthwith either much reduced or wholly swallowed up. To avert the possibility of such an event occurring, the directors were authorised, on the 12th of November, to issue notes without being bound by the conditions of the Act of 1844.⁴

This, though a brief, is, we believe, a sufficiently

Money.

¹ Letter of Mr. Hubbard to the governor of the bank, October 1856.

² Tract by the late Alexander Baring, Esq. (afterwards Lord Ashburton), on the Orders in Council, 1808.

³ The Western Bank, and the City of Glasgow Bank, but especially the former.

⁴ We subjoin a letter by the governor and deputy-governor of the bank, illustrative of the circumstances referred to:—

"Bank of England, December 2, 1857.

"My Lord and Sir,—We have the honour to acknowledge the receipt of your letter of the 27th inst., requesting 'such an explanation with respect to the course which the directors of the Bank of England have pursued in regulating their issues of notes since the 12th inst. as they may be able to furnish for the information of Her Majesty's Government.'

Money. accurate account of the circumstances that led to the suspension of the Act in 1857. The weight to be attached to them will be differently estimated by different individuals. The suspension is believed by some to have been, at least, premature, and others think that probably it might have been avoided. It is alleged that the panic in Scotland had begun to subside previously to the measure being adopted; and it was all but certain that when it had subsided, a considerable portion of the gold that had been sent to Scotland would speedily find its way back to London, and some considerable risk and inconvenience should have been encountered rather than that measures should have been adopted, the effect of which will be to protect speculators and money dealers without capital, and wanting alike in character and conduct, from the consequences of their unjustifiable proceedings. But, at the same time, we admit that the immediate exposure and punishment of these parties, however desirable, was not to be purchased at the risk of a general revulsion. And as the information laid before ministers made them believe that such a calamity was imminent unless the statute of 1844 was suspended, they were bound to act upon that conviction, and to provide *ne quid detrimenti respublica capiat*.

But whatever may be thought of these conclusions, it is at all events certain that the Act of 1844 had nothing whatever to do with the late revulsion. It did not occasion the American stoppage, and under its operation the foreign drain for gold had been entirely stopped; and though it could not prevent the abuses in banking, and the system of rediscounting and overtrading in which so many banks and firms have been engaged, it contributed in no ordinary degree, by preventing the issue of spurious paper, to confine them within comparatively narrow limits, and to lessen the violence of the crisis.

Money. The Act of 1844 is a rule to be enforced in all but extraordinary and unforeseen emergencies, the urgency of which cannot be appreciated beforehand, but must be determined at the moment. But when these occur, it may, like the *Habeas Corpus* Act, be properly suspended. It is mainly calculated to regulate our currency by the exchanges, or through our commercial intercourse with other countries; but it is not applicable, nor is any system of which the convertibility of paper into coin makes a part applicable to a state of internal discredit or panic. Had it existed in 1797, it must have been suspended; and its suspensions in 1847 and 1857 are only to be justified by the state of our domestic affairs making an adherence to principle inexpedient and impracticable. But, whenever the circumstances referred to, that is, when the panic and distrust that occasion the suspension of the Act subside, then it should be revived in its pristine vigour. The *Habeas Corpus* Act is not the less efficient at this moment that it has been repeatedly suspended in periods of danger and difficulty.

Inasmuch, however, as the Act of 1844 has been suspended in cases of emergency, and as there can be no doubt that it will be suspended, if occasion require, in time to come, it may be supposed, perhaps, to be indifferent whether such suspension should be effected as hitherto by the *pro re nata* interference of ministers, or whether a suspensive power should be embodied in the Act. We believe, however, that the present plan is much the best of the two. When government interferes to suspend the Act, the necessity under which they are now placed of applying to Parliament for an indemnity, and the discussions thence arising, are the best securities that can be obtained for the measure not being resorted to rashly, or without a reasonably good cause. But it would be quite another thing did the Act contain a clause authorising suspensions. This would show that

"In complying with this wish it may be well to allude to the position of the Bank of England accounts anterior to the receipt of the letter of the 12th.

"On the 24th of October the bullion in the issue department was £8,777,000; the reserve £4,079,000; the notes in the hands of the public, £19,766,000; the discount and advances, £10,262,000; and the deposits, £16,126,000; the rate of discount at the bank being eight per cent. for bills having not more than 95 days to run.

"In the following week a great shock of credit and a consequent demand on the Bank of England for discounts arose from the failure of the Liverpool Borough Bank, whose rediscounted bills were largely held by the bill-brokers and others in London. The effects of this and other failures, however, up to this time, had not occasioned any alarming pressure on the resources of the bank, or great disquietude in commercial affairs in London.

"On the 5th of November the reserve was £2,944,000, the bullion in the issue department £7,919,000, and the deposits £17,265,000. The rate of discount was advanced to 9 per cent., and on the 10th of November to 10 per cent.

"The Continental drain for gold had ceased, the American demand had become unimportant, and there was at that time little apprehension that the bank issues would be inadequate to meet the necessities of commerce within the legalized sphere of their circulation.

"Upon this state of things, however, supervened the failure of the Western Bank of Scotland and the City of Glasgow Bank, and a renewed discredit in Ireland, causing an increased action upon the English circulation by the abstraction in four weeks of upwards of two millions of gold to supply the wants of Scotland and Ireland; of which amounts more than one million was sent to Scotland and £280,000 to Ireland between the 5th and 12th of November.

"This drain was in its nature sudden and irresistible, and acted necessarily in diminution of the reserve, which on the 11th had decreased to £1,462,000, and the bullion to £6,666,000.

"The public became alarmed, large deposits accumulated in the Bank of England, money dealers having vast sums lent to them upon call were themselves obliged to resort to the Bank of England for increased supplies, and for some days nearly the whole of the requirements of commerce were thrown on the bank. Thus, on the 12th, it discounted and advanced to the amount of £2,373,000, which still left a reserve at night of £581,000.

"Such was the state of the Bank of England accounts on the 12th, the day of the publication of the letter from the Treasury. The demand for discounts and advances continued to increase till the 21st, when they reached their *maximum* of £21,616,000.

"The public have also required a much larger quantity of notes than usual at this season, the amount in their hands having risen on the 21st to £21,554,000.

"The Bank have, since the 12th, under the authority of the letter from the Treasury, issued £2,000,000 of notes in excess of the limits of the circulation prescribed by the Act of 1844, and have passed securities to the issue department to that amount.

"That, however, is not the measure of the amount actually parted with by the Bank, which has not exceeded £928,000, the remainder of the £2,000,000 having been retained as a reserve of notes in the banking department, which, at the same time, also held £407,020 in coin.

"We subjoin a statement of accounts from the 11th of November to the 28th inclusive, from which it will be apparent that the Bank continued to meet all the demands for discounts and advances, on approved securities, to remedy the commercial discredit and distress mentioned in your letter of the 12th inst., 'as occasioned by the recent failure of certain joint-stock banks in England and Scotland, as well as of certain large mercantile firms chiefly connected with the American trade,' and aggravated by the subsequent embarrassment of large joint-stock banks.

"In discounts and advances the sum supplied to the public between the 12th of November and 1st of December amounted in the aggregate to £12,645,000.

"To the Right Hon. the First Lord of the Treasury and the
"Right Hon. the Chancellor of the Exchequer.

SHEFFIELD NEAVE, Governor.
BONAMY DOBREE, Deputy-Governor."

Money.

they were expected, and, indeed, almost invited. Under such circumstances, they would soon come to be regarded as matters of course, and to be resorted to whenever a complaint or cry of monetary pressure was got up. And were such the case, it would be idle to suppose, that either the Act or the convertibility of notes should be maintained for any considerable period. The millennium of the paper-mongers would be at hand. When the checks which with difficulty restrain over-issue, depreciation, and fraud, are repealed or rendered inefficient, what are we to expect but that they should extend their baleful influence on all sides?

If we are right in these statements, it follows that the Act of 1844 should be indefinitely continued with little or no alteration. We are well convinced that all the most important interests of the country will be best secured by such a proceeding.¹

SECT. VI. *Management of the Bank of England.*

Bank-notes made legal tender everywhere except at the bank.

When the charter was renewed in 1833, the notes of the Bank of England were made legal tender everywhere in England except at the bank. Of the wisdom of this regulation no doubt can be entertained. Bank-notes are necessarily always equivalent to bullion; and by making them substitutes for coin at country banks, the demand for the latter during periods of alarm or runs is materially diminished, and the stability of the bank and of the pecuniary system of the country proportionally increased.

Since 1826 the bank has established branches in some of the great commercial towns. The mode and terms of conducting business at which have been described as follows:—

Account of branch banks.

“The branch bank at Swansea (and the same is true of those established in other places) is to be a secure place of deposit for persons having occasion to make use of a bank for that purpose; such persons are said to have *drawing accounts*: to facilitate to the mercantile and trading classes the obtaining discounts of good and unexceptionable bills, founded upon real transactions, two approved names being required upon every bill or note discounted; these are called *discount accounts*. The applications of parties who desire to open discount accounts at the branch are forwarded to the parent establishment for approval, and an answer is generally received in about ten days. When approved, good bills may be discounted at the branch without reference to London. Bills payable at Swansea, London, or any other place where a branch is established, are discounted under this regulation. The dividends on any of the public funds, which are payable at the Bank of England, may be received at the branch, by persons who have opened ‘drawing accounts,’ after signing powers of attorney for that purpose, which the branch will procure from London. No charge is made in this case, except the expense of the power of attorney and the postages incurred in transmitting it. Purchases and sales of every description of government securities are effected by the branch at a charge corresponding to that made by the local bankers where the branch is situated. A commission, including brokerage in London, and all expenses of postage, is charged on paying at the Bank of England bills accepted

Money.

by persons having drawing accounts at Swansea, such bills to be advised by the branch; also for granting letters of credit on London, or on the other branches. The branch grants bills on London, payable at seven days’ date, without acceptance, for sums of £10 and upwards. Persons having drawing accounts at Swansea may order money to be paid at the bank in London to their credit at Swansea, and *vice versa*, at a charge of 6d. in lieu of postage. The branch may be called upon to change any notes issued and *dated* at Swansea; but they do not change the notes of the bank in London, nor receive them in payment, unless as a matter of courtesy where the parties are known. Bank post bills, which are accepted and due, are received at the branch from parties having drawing accounts, and taken to account without any charge for postage; but unaccepted bank post bills, which must be sent to London, are subject to the charge of postage, and taken to account when due. No interest is allowed on deposits. No advance is made by the branch upon any description of landed or other property, nor is any account allowed to be overdrawn. The notes are the same as those issued by the parent establishment, except being dated Swansea, and made payable there and in London. No note issued exceeds the sum of £500, and none are for a less amount than £5.”

But though it might have been advisable to establish offices in Manchester, Birmingham, and one or two more great towns, for the interchange of bank-notes and gold, we much doubt whether the establishment of the branch banks has been advantageous. Speaking generally, it may be laid down that local affairs are best conducted by local agencies; and this is believed to be especially the case in banking. It is a business which is most likely to flourish when those by whom banks are established in country districts belong to those districts, and are well acquainted with the character and pursuits of those with whom they deal.

The Bank of England transacts the whole business of government. “She acts not only,” says Adam Smith, “as an ordinary bank, but as a great engine of state. She receives and pays the greater part of the annuities which are due to the creditors of the public; she circulates exchequer bills; and she advances to the government the annual amount of the land and malt taxes, which are frequently not paid till some years thereafter.”

Bank of England in connection with the government.

The greater part of the paper of the bank has generally been issued in the way of advances or loans to government, upon security of certain branches of the revenue, and in the purchase of Exchequer bills and bullion; but her issue through the medium of discounts and advances to individuals has also been at all times considerable, while during war, and in periods of distress, it is occasionally very great. Generally, however, the directors do not appear to have thought it advisable to enter into any very keen competition with private bankers in the discounting of mercantile paper. And hence it is that the rate of interest charged by the bank for loans being usually equal to, and sometimes rather above the market rate, comparatively few applications are made to her, in ordinary periods, for discounts. But, at the same time, every one who has any reasonable security to offer, knows where they may always be had; while the rate of interest charged by the

Assistance rendered by bank to the mercantile interest.

¹ We earnestly recommend those who may have any doubts in regard to this conclusion, to read and study the evidence of Lord Overstone before the Bank Acts Committee of 1857. It cannot fail to carry conviction to every one in the least familiar with such subjects, and is a most masterly and indeed triumphant vindication of the Act of 1844, and of sound monetary principles. It embraces, discusses, and exhausts the fundamental principles of paper-money and banking. It were much to be wished that it were published separately.

Of the opponents of the Act of 1844, the writers in the *Economist* are at once the most reasonable, ingenious, and able. Those, however, on whom their lucubrations may have made an impression, will probably be restored to the sound faith if they read over the pamphlet of Mr. Arbuthnot of the Treasury. He has shown the fallacy of many of the statements and conclusions of the writers referred to, as well as of others, and has set the practical working of the Act of 1844 in a clear light.

Money.

bank necessarily forms a *maximum* rate which no other establishment can exceed. When, however, any circumstances occur to occasion a pressure in the money market, or a difficulty of obtaining accommodations in the usual channels, the market rate of interest generally rises to the rate fixed by the bank, how high soever that may be, and on such occasions the private bankers, and the public generally, resort to the bank for aid. She then becomes, as it were, a *bank of support*; and has, as such, on various occasions, rendered good service to public credit, and to the commercial interests of the country.

But, at the same time, it must be admitted that the interference of the bank in assisting the commercial interest is a matter that requires the greatest consideration, and that it can only be safely undertaken in rare instances and under very peculiar circumstances. We repeat again, that however a drain for gold may originate, the fact of its existence shows conclusively that gold is more valuable abroad than here, and consequently that the currency is redundant and ought to be diminished. Under such circumstances, it is the imperative duty of the directors, if they would prevent the total exhaustion of their banking reserve, not to fill up the vacuum caused by the exchange of notes for bullion, by the issue of fresh notes. It is at such periods, no doubt, that the applications for assistance are the most urgent; but it is impossible to yield to them, and at the same time to enforce that systematical and continuous reduction of the issues which is indispensable for the safety of the banking department of the bank. She can no longer assist herself as on former occasions, by making fresh issues of paper. And in truth that resource was of no real advantage to her, but the reverse. It tempted her to disregard those great principles and warnings which never can be neglected with impunity. The great commercial crises that took place in 1793, in 1815-16, in 1825, and in 1836-39, were all increased in violence and destructiveness by the bank declining to narrow her issues immediately on the exchange becoming unfavourable, and deferring her repressive action till too late a period.

Methods by which the bank may reduce her issues.

When the bank sets about reducing her issues, she may effect her object in various ways, viz., by rejecting a portion of the bills sent to her for discount, by raising the rate of interest at which she discounts or makes advances, by shortening the dates or *échance* of the bills which she negotiates, and by selling bullion and securities. Of these means, some may be more or less expedient at one time, and some at another. On the whole, however, the first mode, or the rejection of bills, seems to be, in all respects, the most objectionable. The bank will not, of course, discount any bill in regard to the payment of which there can be any reasonable doubt. And when the solidity of the bills offered for discount cannot be objected to, it becomes an invidious, if not an unjust proceeding, to discount some and reject others. Under such circumstances, the true plan is to raise the rate of interest, for while such rise operates equally and universally, it makes rich parties, or those who can avail themselves of other means of accommodation, withhold their demands, and thus effects its object in the fairest and easiest way, and without sacrificing individuals.

Inasmuch, however, as any sudden rise in the rate of discount, especially if it be considerable, is always productive of more or less inconvenience to the mercantile world, it may be proper, when the exchange becomes unfavourable, to endeavour to restore it to par by shortening the dates of bills, and if circumstances will permit, by selling bullion and securities. But, at all events, the redundancy of the currency must be got rid of, and the exchange redressed; and if the other means at the disposal of the

bank be inadequate to effect this object, a rise in the rate of interest should be at once resorted to, and carried to the necessary extent.

Money.

It may be observed, with respect to the sale of securities, that they may be wholly or partly paid by drafts against deposits held by the bank. But, if so, it is clear that, at all events, her debts, or the obligation under which she lies to pay notes or gold to depositors when demanded, will be in so far reduced.

The fact that the applications for discounts at the bank are usually most numerous, when the rate of discount is highest, has made some doubts be entertained in regard to the efficacy of a rise in that rate to raise the value of the currency, and restore an unfavourable exchange to par. But the additional demand for discounts, on the occasions referred to, is most commonly a consequence of the increased difficulty of obtaining them in other quarters; and when the rate of discount becomes unusually high, apprehensions of a revulsion begin to be entertained, and bankers and others carry bills to the bank, not that they may get gold to send abroad, but that they may provide for their own security, by getting a supply of notes or gold, or both, to keep in reserve. And it is further to be observed, that the rise in the rate of interest, whether it be, as it usually is, the result of capital becoming scarcer or more productive, or of a temporary increase in the demand for money, uniformly operates to hinder the exportation of the latter. That such is the case is evinced by what took place in 1825, and in 1836-37. And on the recent occasion, notwithstanding the large sums lent by the bank on bills and advances of one sort or other, the ten per cent. rate of interest charged by her was sufficient to stop the efflux of bullion to the Continent and the United States; and, but for the abuse of credit by some private establishments, the restoration of the exchange to par would have been effected without any internal revulsion.

The Bank of England rarely discounts bills that have more than two, or at most three, months to run, and it were well were this rule generally observed by other establishments. The discounting of bills at long dates is a powerful stimulus to unsafe speculation. When individuals obtain loans which they are not to be called upon to pay for six, twelve, or, perhaps, eighteen months, they are tempted to adventure in speculations which are not expected to be wound up till some proportionally distant period, and as these not unfrequently fail, the consequence is that, when the bills become due, there is commonly little or no provision made for their payment. In such cases the discounters, to avert an imminent loss, sometimes consent to renew the bills. But, while a proceeding of this sort is rarely productive of ultimate advantage to either party, the fact of its having taken place makes other adventurers reckon that, in the event of their speculations proving to be less successful than they anticipated, their bills will be treated in the same manner, and thus aggravates and extends the evil.

In other respects, too, the discount of bills at long dates, or their renewal, or the making of permanent loans, is altogether inconsistent with sound banking principles, for it prevents the bankers from having that command over their resources which is advantageous at all times, and indispensable in periods of difficulty or distress.

In the discounting of bills, a great deal of stress is usually laid, or pretended to be laid, on the distinction between those that arise out of real transactions and those that are fictitious, or that are intended for accommodation purposes. The former are said to be legitimate, while the latter are stigmatised as illegitimate.

Mischievous effects of discounting bills at long dates.

Distinction between real and accommodation bills.

Money.

But Mr Thornton¹ has shown that the difference between these two classes of bills is neither so well marked nor so wide as most persons suppose. A notion seems to be generally entertained that all real bills are drawn against produce of one sort or other, which, or its value, is supposed to form a fund for their payment. Such, however, is not always, nor even most commonly the case. A, for example, sells to B certain produce, for which he draws a bill at sixty days' date. But prices are rising, trade is brisk, or a spirit of speculation is afloat, and in a week or two (sometimes much less), B sells the produce at an advance to C, who thereafter sells it to D, and so on. Hence it may, and in fact frequently does happen, that bills amounting to four, five, or even ten times the value of a quantity of merchandise, have grown out of its successive sales, before the first bill of the series has become due. And not only this, but bills are themselves very frequently rediscounted; and in this case the credit of the last indorser is generally the only thing looked to; and there is not, perhaps, one case in ten in which any inquiries are made in regard to the origin and history of the bills, though they are often of the most questionable description.

On the whole, therefore, it would seem that the real or presumed solidity of the parties signing a bill, and responsible for its payment, is the only safe criterion by which to judge whether it should or should not be discounted. But the fact of a merchant or other trader offering accommodation bills for discount ought unquestionably to excite a suspicion that he is trading beyond his capital. Inquiries of the most searching description should forthwith be instituted; and unless satisfactory explanations are given, his paper should be rejected. On the same principle, the offering of bills for rediscount ought to awaken suspicions of the bankers and others who resort to so questionable a mode of carrying on business. But, except in so far as a feeling of distrust may be thus very properly excited, there does not appear to be anything in an accommodation bill *per se* to hinder it from coming within the pale of negotiability. It is a mode of obtaining a loan from a bank; and when the character of the bill is known to the banker, or is openly declared, it does not appear to be an objectionable mode.

Besides bills avowedly intended for accommodation purposes, another and a different variety of such bills is drawn by parties at a distance from each other, often men of straw, and made to appear as if they were botomed on real transactions. And we are sorry to say, that bills of this sort are always current, and often to a large extent. Of course no person of respectability can be knowingly connected with such bills, which are almost always put in motion either to bolster up some bankrupt concern, or to cheat and defraud the public. But despite the mischief of which they are productive, it appears to be pretty generally supposed that the currency of these bills is an evil which cannot be prevented. There can, however, be no real doubt that it may, at all events, be very greatly diminished; and this desirable result would be effected were it enacted that all bills shall henceforth bear upon their face what they really are. That those that are intended for accommodation purposes shall have at their head the words "*Accommodation Bill*;" and that those only shall bear to be for "value received" that have grown out of *bond fide* transfers of property. An enactment of this sort could not be felt as a grievance by any one unless he had a fraudulent purpose in view. And were the impressing of a false character on a bill made a criminal offence punishable by

three years' imprisonment, or some such penalty, there is every probability that a formidable check would be given to the issue of spurious bills, and to the manifold abuses to which the practice gives rise.

Bill-discounters who have got fictitious paper on their hands, and attempt, as has been done, to get rid of it by concealing its character, or representing it in a favourable light, make themselves parties to the fraud. Such conduct is so very flagitious, that when it can be fairly brought home to the parties, it should subject them to the severest penalties.

The rates of discount charged by the bank, since its establishment in 1694, down to the present time (1857), have been as follows:—

Money.

1747	5 "	1853	8 "
1753	4½ "	1856	9½ "

Bank does not allow interest on deposits. The Bank of England does not allow, either at the head office in London, or at her branches, any interest on deposits; and in doing so she acts wisely. Notwithstanding the non-payment of interest, she has often very large amounts of deposits on her hands, and were she to pay interest, the probability is that they would be very greatly increased, and might, in periods of difficulty, seriously compromise her safety. At present the bank may either retain deposits or invest them in those securities from which they may be most easily withdrawn. But if she allowed interest, the case would be different, and she would be obliged to look quite as much or more to the profits to be made by investments as to the facility of repossessing herself of funds. We beg, in corroboration of what has now been stated, to draw the reader's attention to the following extract from the evidence of Mr Weguelin, late governor of the bank, before the Committee of 1857:—

"We," said he, "at the Bank of England, have always considered that the proper functions of a banker were to keep the spare cash of his customer, such cash as his customer required for his daily expenditure, for the sudden demands of his business, and any accidental accumulation which might happen before the customer had occasion to invest it. That is contrasted with the system pursued by the joint-stock banks. The joint-stock bank invites a large deposit by offering a certain rate of interest for the deposit; in point of fact, the joint-stock bank becomes the investor of the money instead of the customer. The customer of a joint-stock bank does not himself invest his own money, but he employs the joint-stock bank to do it, taking the guarantee of the joint-stock bank, and taking, possibly, a lower rate of interest. Now that system, if applied to the Bank of England, would be, I think, very prejudicial to the public interests. It would, in the first place, force upon the Bank of England to invest its reserves much more closely than it does now. If it had to pay interest upon its deposits, it could only do so by investing them in some securities that would pay a higher rate of interest than that which it pays. Its deposits also are of that particular character which would render it still more inexpedient that they should be closely invested. They consist, in the first place, of government deposits, which rise from a low rate at one period of a quarter up to five or six millions higher at another period of a quarter, and again collapse to a very low rate at another period. Again, the private deposits consist, to a certain extent, of the deposits of the bankers and the joint-stock banks of London. Those deposits are the amounts which those bankers require to work their own business. Consequently, they are not

deposits which should be very closely invested by the Bank of England. In times when there is a great accumulation of deposits in the Bank of England, it is because the public are not able at those times to find investments to their mind to employ those deposits; and consequently, it is not at all likely that the Bank of England, if that is the case with the public generally, will be able to find investments which the public themselves have not been able to do. All these reasons combined would lead me to think that to force a system upon the Bank of England by which it should be obliged to employ its deposits very closely—much more closely than it does at present—would be not only prejudicial and unsafe as regards the Bank of England, but would be prejudicial to the public interest."—*Quest. 159.*

The truth is, that the whole subject of deposits is beset with difficulties. The extent to which it has been already carried has deeply endangered the stability of the banking system, and we have seen that it is indispensable it should be subjected to regulation.

Previously to 1786, the bank received an allowance for trouble in paying the dividends, superintending the transfer of the stock, &c., of the national debt of £562:10s. a million on its amount. In 1786 this allowance was reduced to £450 a million, the bank being, at the same time, entitled to a considerable allowance for her trouble in receiving contributions on loans, lotteries, &c. This, though long regarded as a very improvident arrangement on the part of the public, was acquiesced in till 1808, when the allowance on account of management was reduced to £340 per million on £600,000,000 of the public debt, and to £300 per million on all that it exceeded that sum, exclusive of some separate allowances for annuities, &c. The impression, however, was still entertained that the allowances for management should be further reduced, and this has been effected in the interim.

Exclusive of her functions as public banker, and manager of the public debt, the Bank of England is connected with government through the circulation. We have seen that she is entitled to issue upwards of £14,000,000 upon securities, that is, on the credit of the funds she has lent to government. But for these she receives about 3 per cent. interest, and such being the case, the public is clearly entitled to a portion, if not to the whole amount of the profits realised by the bank on the issue of these £14,000,000. It is difficult to say how much this may amount to. The issue department of the bank seldom re-issues notes, but for the most part destroys them as soon as they are returned to it. This practice is said to be necessary to enable the bank to obviate fraud, by keeping a proper account of the numbers of the notes afloat. An opinion is, however, pretty generally entertained that this might be effected by a less expensive process than that which is now resorted to. And, certainly, it seems to be a very wasteful proceeding, that a quantity of newly manufactured notes issued by the bank in the forenoon, and returned to her in the afternoon, should not be reissued, but consigned to the flames. The Scotch banks are justly censurable for keeping their notes too long afloat, but this is running with a vengeance into the opposite extreme.

But, as it is, the cost of maintaining an issue of £14,000,000 is estimated by the bank at about £113,000 a year; and taking the gross profits of the issue at 3 per cent., or £420,000, the nett profits may be estimated at £307,000 a year; and of this sum the bank pays to government £180,000, viz., £60,000 in lieu of the old charge for stamp duty, abolished in 1844, and a further sum of £120,000, leaving the bank £127,000 for her share of the profits. And so long as the cost of the issues remains at about its present amount, we do not know that there

Money.

is much to object to in this arrangement. Probably, however, were the allowance to government further increased by some £50,000 or £60,000, the bank might find means, without injury to the public, of re-issuing her notes, or of otherwise reducing the cost of their circulation. During the year ended the 31st March 1856, the payments made to the bank for managing the national debt and annuities amounted to £95,875.

It should be observed that the responsibility and expense incurred by the bank, in managing the public debt, are very great. The temptation to the commission of fraud, in transferring stock from one individual to another, and in the payment of the dividends, is well known; and notwithstanding the skilfully devised system of checks adopted by the bank for its prevention, she has frequently sustained very great losses by forgery and otherwise. In 1803 the bank lost, through a fraud committed by one of her principal cashiers, Mr Astlett, no less than £340,000; and the forgeries of Fauntleroy, the banker, cost her a still larger sum! At an average of the ten years ending with 1831, the bank lost, through forgeries on the public funds, £40,204 a year.—(*Report on Bank Charter, Appen. p. 165*).

Dead weight.

Besides the transactions alluded to, the bank entered, on the 20th of March 1823, into an engagement with government with respect to the public pensions and annuities, or, as they have been more commonly termed, the *dead weight*. At the end of the war, the naval and military pensions, superannuated allowances, &c., amounted to above £5,000,000 a-year. They would, of course, have been gradually lessened, and ultimately extinguished, by the death of the parties. But it was resolved in 1822 to attempt to spread the burden equally over the whole period of *forty-five* years, during which it was calculated the annuities would continue to decrease. To effect this purpose, it was supposed that, upon government offering to pay £2,800,000 a-year, for forty-five years, capitalists would be found who would undertake to pay the entire annuities, according to a graduated scale previously determined upon, making the first year a payment of £4,900,000, and gradually decreasing the payments until the forty-fifth and last year, when they were to amount to only £800,000. This supposition was not, however, realised. No capitalists were found willing to enter into such distant engagements. But in 1823 the bank agreed, on condition of receiving an annuity of £585,740 for *forty-four* years, commencing on the 5th of April 1823, to pay, on account of the pensions, &c., at different specified periods, between the years 1823 and 1828, both inclusive, the sum of £13,089,419.—(4 *Geo. IV. c. 22*).

Mode of transacting banking business at the bank.

Formerly the business transacted at the bank was so much encumbered with forms and conditions, that the generality of merchants and ordinary people rarely thought of employing her to keep their money or make their payments. But in this respect an entire change has been effected. Cheques, the minimum amount of which was formerly £10, may now be drawn of any amount, great or small; and all sorts of banking business is conducted with facility and dispatch, and, we may add, with perfect security.

The bank opens banking accounts, or, as they are called, "drawing accounts," for the safe custody, and the receipt and payment of cash, not only with merchants and traders, but with all persons who choose to keep their money at a banker's, and to draw cheques against it. The bank also takes charge of their customers' bills of exchange, exchequer bills, and other securities, and does all that is needful either in the collection of bills of

exchange, the exchange of exchequer bills, or the receipt of dividends, and so forth, free of any charge. Plate-chests, and deed and security boxes, may be deposited, free of expense, by customers, for safe custody. The bank looks to the average balance of cash on each account, to compensate for the trouble and expense of keeping it, and in this respect the requirements of the bank are certainly not greater than those of ordinary bankers. No particular sum is required to be lodged on opening an account; it is only necessary that the party should be known as respectable, and in a condition to require a banking account. But the bank receives and holds sums of money for safe custody for parties who have no current accounts.

The following are the regulations under which accounts are conducted:—

1. All letters should be addressed to the chief cashier.
 2. It is desirable that drafts should be drawn upon cheques furnished by the bank.
 3. Cheques upon city bankers, eastward of King Street, Cheapside,
Paid in by 12 o'clock may be drawn for after 1.
Do. 2 o'clock " " " after 3.
 4. Cheques paid in after 2, and before 3 o'clock, and cheques upon all other London bankers paid in before 12 o'clock, may be drawn for on the following morning.
 5. Cheques paid in after 3 o'clock are sent out at 9 the following morning, and may be drawn for as soon as received.
 6. Dividend warrants are received at the drawing office until 4 o'clock in the afternoon for all persons having accounts at the bank.
 7. It is requested that notice be given at the drawing office of bills accepted payable at the bank, with the date of their maturity.
 8. Persons keeping a drawing account with the bank (although not having a discount account) may tender bills for discount through the drawing office. Application for discounts, or for advances on stock, exchequer bills, &c., must be made before 2 o'clock.
 9. Bills of exchange and notes not paid when due, will be noted.
 10. The bank will make purchases or sales of British or foreign securities upon an order in writing addressed to the chief cashier; and dividends on stock may be received under powers of attorney granted to the cashiers of the bank.
 11. Exchequer bills, bonds, railway debentures, or any other securities may be deposited, and the interest, when payable, will be received and placed to account.
 12. Credits paid in to account are received without the bank-book, and are afterwards entered therein without the party claiming them.
 13. Notes of country bankers, payable in London, are sent out the same day for payment if paid in before 3 o'clock.
 14. The pass-books should be left at the drawing office, at least once a month, to be written up.
 15. Where post-bills are required, or a payment is to be made to any office of the bank by cheque on the Bank of England, the cheque must be presented at the office upon which it is drawn, and exchanged for an order on the post-bill office, or on the office at which the payment is to be made.
 16. Cash-boxes taken in, contents unknown, for such parties as keep accounts at the Bank.
 17. A person having a drawing account may have a discount account; but no person can have the latter without at the same time having the former. When a discount account is opened, the signatures of the parties are entered in a book kept for that purpose, and powers of attorney are granted empowering the persons named in them to act for their principals. Bills of exchange having more than 95 days to run are not eligible for discount.
- N.B.*—All changes in the residence of persons keeping cash at the bank are requested to be made known at the drawing office; and it is particularly requested not to offer any gratuities to the clerks of the banking offices, such gratuities being strictly forbidden.
- There are no holidays at the bank except Christmas and Good Friday.

* This column does not (as it ought to have done) include the notes in the banking department of the Bank of England. The latter are given in Table No. IV.

Tables.

No. IV.—ACCOUNT of Bank of England Notes Issued in each Month of each Year from 1850 to 1856 inclusive, showing the Numbers held by the Public and by the Bank, with the Amounts of Bullion, Securities, and Deposits held by the latter; and showing, also, the Discounts and Advances made by the Bank, and the Rate of Interest.

Tables.

	BANK NOTES ISSUED.		Amount of Bullion.	Government Securities.	Other Securities.	Public Deposits.	Other Deposits.	Minimum Rate of Interest.	Discounts and Advances.
	Held by the Public.	Held in Reserve by the Bank.

Money.

The amount of notes afloat varies from time to time, with the varying condition of the country, the state of credit, and so forth. It may, however, in ordinary years, be estimated as follows, viz.—

Issued by Bank of England	£28,000,000
„ Private banks in England	3,700,000
„ Joint-stock banks in England	3,050,000
„ Scotch banks	4,000,000
„ Irish banks	7,000,000
Total Issues	£45,750,000

Of this sum, from five to six millions is usually in the till of the banking department of the bank.

SECT. VII.—Banks (Scotch).

The Act of 1708, preventing more than six individuals from entering into a partnership for carrying on the business of banking, did not extend to Scotland. In consequence of this exemption, several banking companies, with numerous bodies of partners, have existed, for a lengthened period, in that part of the empire.

The Bank of Scotland was projected by Mr. John Holland, merchant, of London, and was established by Act of the Scotch Parliament (Will. III. Parl. 1, § 5) in 1695, by the name of the Governor and Company of the Bank of Scotland. Its original capital was £1,200,000 Scotch, or £100,000 sterling, distributed in shares of £1000 Scotch, or £83:6:8 sterling, each. The Act exempted the capital of the bank from all public burdens, and gave it the exclusive privilege of banking in Scotland for 21 years. The objects for which the bank was instituted, and its mode of management, were intended to be, and have been, in most respects, similar to those of the Bank of England. The responsibility of the shareholders is limited to the amount of their shares.

The capital of the bank was increased to £200,000 in 1744, and was enlarged by subsequent Acts of Parliament, the last of which (44 Geo. III. c. 23) was passed in 1804, to £1,500,000, its present amount. Of this sum £1,000,000 has been paid up. The last-mentioned Act directed that all sums relating to the affairs of the bank should henceforth be rated in sterling money; that the former mode of dividing bank stock by shares should be discontinued; and that, for the future, it should be transferable in sums or parcels of any amount. On the union of the two kingdoms in 1707, the Bank of Scotland undertook the recoinage, and effected the exchange of the currency in Scotland. It was also the organ of government in the issue of the new silver coinage in 1817.

The Bank of Scotland is the only Scotch bank constituted by Act of Parliament. It began to establish branches in 1696, and issued notes for one pound so early as 1704. The bank also began, at a very early period, to receive deposits on interest, and to grant credit on cash-accounts, a minute of the directors with respect to the mode of keeping the latter being dated so far back as 1729. It is, therefore, entitled to the credit of having introduced and set on foot the distinctive principles of the Scotch banking system, which, whatever may be its defects, is perhaps superior to most other systems hitherto established. Generally speaking, the Bank of Scotland has been cautiously and skilfully conducted; and there can be no doubt that it has been productive, both directly and as an example to other banking establishments, of much public utility and advantage.

It may be worth mentioning, that the Act of Will. III. establishing the Bank of Scotland, declared that all foreigners who became partners in the bank should, by doing so, become, to all intents and purposes, naturalised Scotchmen. After being for a long time forgotten, this clause was taken advantage of in 1818, when several

Bank of Scotland.

Money. aliens acquired property in the bank in order to secure the benefit of naturalisation. But after being suspended, the privilege was finally cancelled in 1822.

We subjoin an *official* abstract of the constitution and objects of the Bank of Scotland, printed for the use of the proprietors;—the terms and mode of transacting business are, of course, sometimes altered, according to circumstances.

I. The Bank of Scotland is a public national establishment; erected and regulated by the legislature alone: and expressly as a public bank in this kingdom; for the benefit of the nation, and for the advancement of agriculture, commerce, and manufactures; and for other objects of public policy.—(Will. Parl. 1, § 5; 14 Geo. III. c. 32; 24 Geo. III. c. 8; 32 Geo. III. c. 25; 34 Geo. III. c. 19; 44 Geo. III. c. 23.)

II. The statutory capital is at present £1,500,000 sterling. It is raised by voluntary subscription; and has been subscribed for. £1,000,000 has been called for, and paid in.—(44 Geo. III. c. 23.)

III. Subscribers, if not under obligations to the bank, may, at pleasure, transfer their right. If under obligation to the bank, the obligation must be previously liquidated; or the proceeds of the sale, at a price to the satisfaction of the directors, must be applied towards such liquidation. Transfers are made by a short assignment and acceptance thereof, both in a register appointed for that purpose. The expense, beside the government stamp, is 11s.—(Will. Parl. 1, § 5.)

IV. Bank of Scotland stock may be acquired, in any portions, by any person, community, or other lawful party whatsoever; without selection, exclusion, or limitation of numbers.—(Will. Parl. 1, § 5; 44 Geo. III. c. 23.)

V. Bank of Scotland stock may be conveyed by will, and, if specially mentioned, without expense of confirmation. It cannot be arrested: the holder's right may be adjudged. Dividends may be arrested.—(Will. Parl. 1, § 5.)

VI. The Bank of Scotland is a public corporation by Act of Parliament. The bank's transactions are distinct from those of the stockholders: and theirs from those of the bank.—(Will. Parl. 1, § 5.)

VII. The establishment is expressly debarred from any other business than that of banking.—(Will. Parl. 1, § 5.)

VIII. The management is vested, by statute, in a governor, deputy governor, twelve ordinary, and twelve extraordinary directors. They are chosen annually, on the last Tuesday of March, by the stockholders having £250 of stock or upwards. Those above £250, have a vote for every £250, to £5000, or 20 votes. No person can have more than 20 votes. The governor must hold, at least, £2000 of stock; the deputy governor £1500; and each director £750. They swear to be equal to all persons; and cannot hold any inferior office in the bank.—(Will. Parl. 1, § 5; 14 Geo. III. c. 32; 44 Geo. III. c. 23.)

IX. The executive part is conducted by a treasurer, secretary, and other public officers, all sworn. Those having the official charge of cash find due security.—(Will. Parl. 1, § 5.)

X. The board of directors sits for the general administration of the bank, at the bank's public head office in Edinburgh. The local business of that district is also conducted at that office. For the local business in the other parts of the kingdom, the bank has its regular public offices in the principal towns. At each of these offices there is the bank agent or cashier, who gives due security, and conducts the bank's business for that district in the manner after mentioned.—(Will. Parl. 1, § 5.)

XI. The bank takes in money at all its public offices, on deposit receipts or on current deposit accounts. At the head-office drafts on the branches, and at the branches drafts on the other branches and on the head-office are granted. Both at the head-office and branches drafts are granted on the London, Dublin, and English and Irish provincial correspondents of the bank. All receipts and drafts are on the bank's engraved forms, and bear to be granted "for the Bank of Scotland" or "for the Governor and Company of the Bank of Scotland." At the head office official documents are signed by the treasurer, and at the branches by the agents, and all are countersigned.

Remittances can be made to the principal colonial and continental towns; and bills, payable in the colonies, and in foreign countries, can be negotiated through the bank.—(*Resolution of Court, 1793, as since modified.*)

N.B.—The bank has always allowed interest on deposits, at a rate varying according to circumstances. At present (November 1857) it is 4 per cent. *Money.*

XII. Bills on London, Edinburgh, or any town in the United Kingdom, are discounted at all the bank's public offices. The bank's agents judge, in ordinary cases, of the bills presented; so that parties meet with no delay. The bank does not re-issue the bills which it has discounted.—(*Resolution of Court, 23d Feb. 1789, and Subsequent Modifications.*)

XIII. Government stock and other public funds may be purchased or sold, and dividends thereon may be received through the Bank.

XIV. The bank gives credit on cash accounts at any of its offices, on bond, with security. The security may be personal co-obligants, or such other security as may be specially agreed on. Applications for cash accounts are given in to the office where the cash account is wanted, and must specify the credit desired, and the security proposed; and the individual partners, where copartneries are proposed. Cash accounts are granted by the directors only; and are not recalled unless by their special authority. It is understood that these credits are not used as dead loans, to produce interest only. In the fair course of business, the advantage of the bank is consulted by an active circulation of its notes, and by frequent repayments to it in a way least affecting that circulation.—(*Resolution of Court, 6th Nov. 1729, and 23d Feb. 1789.*)

XV. The Bank's dividend has been for some time 8 per cent. per annum on its paid-up capital of £1,000,000 sterling. The dividends are paid regularly twice a year, without expense. They may be drawn either at the bank's head office, or at any of its other offices, as most agreeable to the stockholder.

The above may suffice as a general outline of the mode in which the business of banking is conducted in Scotland.

The *Royal Bank of Scotland* was established in 1727. Its original capital of £151,000 has been increased to £2,000,000.

The *British Linen Company* was incorporated in 1746, for the purpose, as its name implies, of undertaking the manufacture of linen. But the views in which it originated were speedily abandoned; and it became a banking company only. Its capital amounts to £1,000,000.

None of the other banking companies established in Scotland are chartered associations with limited responsibility, the partners being liable, to the whole extent of their fortunes, for the debts of the firms. Some of them, such as the Edinburgh and Glasgow Bank, the National Bank, the Western Bank, the Commercial Bank, &c., have very numerous bodies of partners. Their affairs are uniformly conducted by a Board of Directors, annually chosen by the shareholders.

The Bank of Scotland began, as already stated, to issue £1 notes so early as 1704; and their issue has since been continued without interruption. "In Scotland," to use the statement given in the Report of the Committee of the House of Commons of 1826, on the Promissory Notes of Scotland and Ireland, "the issue of promissory notes payable to the bearer on demand, for a sum of not less than 20s., has been at all times permitted by law; nor has any act been passed limiting the period for which such issue shall continue legal in that country."

All the Scotch banks receive deposits of so low a Deposits value as £10, and sometimes lower, and allow interest upon them.

The interest allowed by the banks upon deposits varies, from time to time, according to the variations in the current rate of interest. At present (1857) it amounts to 4 per cent. And it has been estimated, by the best authorities, that the aggregate amount of the sums deposited with the Scotch banks was, previously to the late panic, little, if any thing, under £50,000,000.

Money.

The following TABLE exhibits an account of the different Scotch Banks, their Partners, Branches, Authorised Circulation, Actual Circulation, Coin, &c., in 1856 (from Oliver & Boyd's Almanac).

A witness, connected for many years with different banks in Scotland, and who had experience of their concerns at Stirling, Edinburgh, Perth, Aberdeen, and Glasgow, being examined by the Commons' Committee of 1826, stated that more than half the deposits in the banks with which he had been connected were in sums from ten pounds to two hundred pounds. Being asked what class of the community it is that makes the small deposits, he gave the following answer; from which it appears that the mode of conducting this branch of the banking business in Scotland has long given to that country most part of the benefits derivable from the establishment of savings banks.

"Question. What class of the community is it that makes the smallest deposits?"

"Answer. They are generally the labouring classes in towns like Glasgow: in country places like Perth and Aberdeen, it is from servants and fishermen, and that class of the community who save small sums from their earnings, till they come to be a bank deposit. There is now a facility for their placing money in the Provident Banks, which receive money till the deposit amounts to £10. When it comes to £10 it is equal to the minimum of a bank deposit. The system of banking in Scotland is an extension of the Provident Bank system. Half-yearly or yearly those depositors come to the bank, and add the savings of their labour, with the interest that has accrued upon the deposits from the previous half-year or year, to the principal; and in this way it goes on, without being at all reduced, accumulating (at compound interest) till the depositor is able either to buy or build a house, when it comes to be £100, or £200, or £300, or till he is able to commence business as a master in the line in which he has hitherto been a servant. A great part of the depositors of the bank are of that description, and a great part of the most thriving of our farmers and manufacturers have arisen from such beginnings."

Cash-accounts.

The loans or advances made by the Scotch banks are either in the shape of discounts, or upon cash-credits, or, as they are more commonly termed, *cash-accounts*.

A cash-credit is a credit given to an individual by a banking company for a limited sum, seldom under £100 or £200, upon his own security, and that of two or three

individuals approved by the bank, who become sureties for its payment. The individual who has obtained such a credit is enabled to draw the whole sum, or any part of it, when he pleases, replacing it, or portions of it, according as he finds it convenient; interest being charged upon such part only as he draws out. "If a man borrows £5000 from a private hand, besides that it is not always to be found when required, he pays interest for it whether he be using it or not. His bank credit costs him nothing, except during the moment it is of service to him, and this circumstance is of equal advantage as if he had borrowed money at a much lower rate of interest." —(*Hume's Essay on the Balance of Trade*.) This, then, is plainly one of the most commodious forms in which advances can be made. Cash-credits are not, however, intended to be a *dead loan*; a main object of the banks in granting them is to get their notes circulated, and they do not grant them except to persons in business, or to those who are frequently drawing out and paying in money.

The system of cash-credits has been very well described in the Report of the Lords' Committee of 1826 on Scotch and Irish Banking. "There is also," say their Lordships, "one part of their system which is stated by all the witnesses (and, in the opinion of the Committee, very justly stated) to have had the best effects upon the people of Scotland, and particularly upon the middling and poorer classes of society, in producing and encouraging habits of frugality and industry. The practice referred to is that of cash-credits. Any person who applies to a bank for a cash-credit is called upon to produce two or more competent sureties, who are jointly bound; and, after a full inquiry into the character of the applicant, the nature of his business, and the sufficiency of his securities, he is allowed to open a credit, and to draw upon the bank for the whole of its amount, or for such part as his daily transactions may require. To the credit of the account he pays in such sums as he may not have occasion to use, and interest is charged or credited upon the daily balance, as the case may be. From the facility which these cash-credits give to all the small transactions of the country, and from the opportunities which they afford to persons who begin business with little or no capital but their character, to employ profitably the

* The capital of the Banks marked with an asterisk is not in shares, but in stock transferable to any amount.

† These banks stopped payments in November 1857. The latter, however, has resumed business.

Money.

minutest products of their industry, it cannot be doubted that the most important advantages are derived to the whole community. The advantage to the banks who give these cash-credits arises from the call which they continually produce for the issue of their paper, and from the opportunity which they afford for the profitable employment of part of their deposits. The banks are indeed so sensible that, in order to make this part of their business advantageous and secure, it is necessary that their cash-credits should (as they express it) be frequently operated upon, that they refuse to continue them unless this implied condition be fulfilled. The total amount of their cash-credits is stated by one witness to be £5,000,000, of which the average amount advanced by the banks may be one-third."

The expense of a bond for a cash-credit of £500 is 12s. 6d. stamp duty, and a charge of from 5s. to 10s. 6d. per cent. for preparing it.

Stability of the Scotch banks.

There have been, until lately, comparatively few failures among the Scotch banks. In 1793 and 1825, when so many of the English banks were swept off, there was not a single establishment in Scotland that gave way. This superior solidity appears to have been owing to various causes, partly to the banks having, for the most part, large bodies of partners, who, being conjointly and individually bound for the debts of the companies to which they belong, go far to render their ultimate security all but unquestionable; and partly to the facility afforded by the law of Scotland, of attaching a debtor's property, whether it consist of land or movables, and making it available for the payment of his debts. This last-mentioned circumstance was referred to as follows, in the report already alluded to.

"A creditor in Scotland is empowered to attach the real and heritable, as well as the personal estate of his debtor, for payment of personal debts, among which may be classed debts due by bills and promissory notes; and recourse may be had, for the purpose of procuring payment, to each description of property at the same time. Execution is not confined to the real property of a debtor merely during his life, but proceeds with equal effect upon that property after his decease.

"The law relating to the establishment of records gives ready means of procuring information with respect to the real and heritable estate of which any person in Scotland may be possessed. No purchase of an estate in that country is secure until the sasine (that is, the instrument certifying that actual delivery has been given) is put on record, nor is any mortgage effectual until the deed is in like manner recorded.

"In the case of conflicting pecuniary claims upon real property, the preference is not regulated by the date of the transaction, but *by the date of its record*. These records are accessible to all persons; and thus the public can with ease ascertain the effective means which a banking company possesses of discharging its obligations; and the partners in that company are enabled to determine, with tolerable accuracy, the degree of risk and responsibility to which the private property of each is exposed."

But, on the whole, we are inclined to think that the long familiarity of the inhabitants with banks and paper money, and the less risk that has attended the business of banking in Scotland, have been the principal causes of the greater stability of the Scotch banks. Latterly, however, owing to the rapid growth of Glasgow, Dun-

dee, and other commercial towns, the risk attending banking in Scotland has materially increased. And while hazard has been augmenting on the one hand, there appears, on the other, to have been a still more rapid decrease of that cautious policy that was supposed to be a characteristic of Scotch bankers. In the recent crisis two of the principal Scotch banks, the head-quarters of which were in Glasgow, were compelled to stop payments. They had very large capitals, the Western Bank £1,500,000, and the City of Glasgow Bank £1,000,000, with a great many branches, large amounts of deposits, and very numerous and wealthy proprietary bodies. Had their management displayed anything like ordinary skill and prudence, they might have gone triumphantly through a far more serious trial. But it was characterised, especially that of the Western Bank,¹ by the most marvellous folly and recklessness. Having advanced immense sums to a few firms that never were entitled to any considerable credit, the Western Bank was so crippled that, for a lengthened period before their stoppage, they were reduced to the miserable expedient of sending up the bills they had discounted in Glasgow to be rediscounted in London; and when this resource failed them, and the other banks declined to come forward to their assistance, they had nothing for it but to shut their doors. On the affairs of the bank being investigated by a committee appointed for the purpose, it was found that they were in a much worse state than any one could have anticipated. Their entire losses are said to amount to the enormous sum of £2,020,584; so that, in addition to the capital and rest of the bank, making together £1,715,892, which have wholly disappeared, a further deficiency of £304,692 will have to be provided for! No such gigantic failure has ever occurred in Scotland; and it is not easy to imagine the misery of which it cannot fail to be productive.

Eventually, there can be no doubt that the creditors of the Western Bank will be fully paid, for the proprietary comprises some of the most opulent individuals in Scotland. Unhappily, however, it also comprises hundreds belonging to the middle and lower classes, who were tempted, by the dividend of 9 per cent., and the assurance of prosperity, to embark in the concern. And a loss that may be of little or no consequence to the former may send the latter to the workhouse.

The ruin in which the bank has been involved did not come suddenly upon it. On the contrary, it has been accumulating for years. And yet the directors took no steps, or none that were efficient, to arrest the progress of the evil; nor did they apprise their confiding constituents of the perilous condition into which the bank had got. Concealment was practised to the very last moment, till the concern was irretrievably sunk in the abyss of bankruptcy. It is much to be wished that directors who have so acted were really responsible for their conduct. No charge of corruption is brought against them; but their inattention to, and neglect of, the important interests committed to their charge, has been wholly inexcusable. They were bound, on undertaking the office of directors, to bestow unremitting care and diligence upon the performance of the duties which it imposed on them. They might neglect their own business; but they could not, without a flagrant breach of trust, neglect the duties they had undertaken to discharge on account of others. This, however, is precisely what they have done. They appear to have selected the most reckless and incompe-

Money.

Bankruptcy of the Western Bank.

¹ The management of the City of Glasgow Bank, though in many respects blameworthy, has been, as compared with that of the Western Bank, prudent and skilful. It has recommenced business; and it is to be hoped that its managers will profit by the lesson they have received.

Money. tent managers, and then to have given them *carte blanche*. Whatever such conduct may be in law, it is, morally and politically, in the highest degree culpable. Hundreds have been sent to the antipodes and the treadmill for offences that were comparatively innocuous. No doubt, however, the grand source of mismanagement in banks and other associations is to be found in the apathy of the shareholders, in the blind and often undeserved confidence they place in those who are, no matter how, at the head of their concerns. If those who may be ruined by the proceedings of their own officers and servants will not look after them, it were idle to attempt to throw such a duty upon others.

In a public point of view the stoppage of the Glasgow banks was productive of the very worst results. By creating a panic, and occasioning a heavy internal demand for gold, it may indeed be said to have been the main cause of the suspension of the Act of 1844.

£1 notes
should
be sup-
pressed.

The recent occurrences would seem to show that the time for the suppression of £1 notes in Scotland has arrived. The panic, which has had such mischievous results, principally prevailed among the smallest class of depositors and the holders of £1 notes. Everybody in the least degree familiar with money matters knew that, however the Western Bank might have been perverted and abused, its solvency could admit of no doubt. But such considerations could not be expected to influence the lower classes, who are the principal holders of £1 notes, and to whom large sums are due by the savings and other banks; and hence the run on the Western Bank, the City of Glasgow Bank, and on other banks whose character stood highest. It may be fairly presumed that if £1 notes be permitted to continue in circulation, the like results will take place on future occasions. And with a view to obviate their recurrence, and to strengthen the basis of the currency, sovereigns should be introduced instead of £1 notes. The change would occasion little, if any, immediate loss to the banks, and the increased security of which it would be productive would be as advantageous to them as it would be to the other classes of the community.

We also think that it would be good policy to make Bank of England notes legal tender in Scotland and Ireland as well as in England. This might occasionally be a convenience to all parties, and it would tend to familiarise the public in those parts of the empire to the use of Bank of England notes, which ought eventually to be the only notes in circulation.

SECT. VIII.—*Banking in Ireland.*

Banking
in Ireland.

"In no country, perhaps," says Sir Henry Parnell, "has the issuing of paper money been carried to such an injurious excess as in Ireland. A national bank was established in 1783, with similar privileges to those of the Bank of England, in respect to the restriction of more than six partners in a bank; and the injury that Ireland has sustained from the repeated failure of banks may be mainly attributed to this defective regulation. Had the trade of banking been left as free in Ireland as in Scotland, the want of paper-money that would have arisen with the progress of trade, would in all probability have been supplied by joint-stock companies, supported with large capitals, and governed by wise and effectual rules.

"In 1797, when the Bank of England suspended its payments, the same privilege was extended to Ireland; and after this period the issues of the Bank of Ireland

were rapidly increased. In 1797, the amount of the notes of the Bank of Ireland in circulation was £621,917; in 1810, £2,266,471; and in 1814, £2,986,999.

Money.

"These increased issues led to corresponding increased issues by the private banks, of which the number was fifty in 1804. The consequence of this increase of paper was its great depreciation; the price of bullion and guineas arose to ten per cent. above the mint price; and the exchange with London became as high as eighteen per cent., the par being 8½. This unfavourable exchange was afterwards corrected, not by any reduction in the issues of the Bank of Ireland, but by the depreciation of the British currency in the year 1810, when the exchange between London and Dublin settled again at about par. (See ART. EXCHANGE.)

"The loss that Ireland has sustained by the failure of banks may be described in a few words. It appears, by the Report of the Committee on Irish Exchanges in 1804, that there were, at that time, in Ireland fifty registered banks. Since that year a great many more have been established, but the whole have failed, one after the other, involving the country from time to time in immense distress, with the following exceptions:—*First*, a few that withdrew from business; *secondly*, four banks in Dublin; *thirdly*, three at Belfast; and, *lastly*, one at Mallow. These eight banks, with the new Provincial Bank and the Bank of Ireland, are the only banks now (1827) existing in Ireland.

"In 1821, in consequence of eleven banks having failed nearly at the same time, in the preceding year, in the south of Ireland, government succeeded in making an arrangement with the Bank of Ireland, by which joint-stock companies were allowed to be established at a distance of fifty miles (Irish) from Dublin, and the bank was permitted to increase its capital from 2½ to 3 millions sterling. The Act 1 and 2 Geo. IV. c. 72, was founded on this agreement. But ministers having omitted to repeal in this Act various restrictions on the trade of banking that had been imposed by 33 Geo. II. c. 14, no new company was formed. In 1824, a party of merchants of Belfast, wishing to establish a joint-stock company, petitioned Parliament for the repeal of this Act of Geo. II.; and an Act was accordingly passed in that session, repealing some of its most objectionable restrictions. (5 Geo. IV. c. 73.)

"In consequence of this Act, the Northern Bank of Belfast was converted into a joint-stock company, with a (nominal) capital of £500,000, and commenced business on the 1st of January 1825. But the restrictions of 33 Geo. II., and certain provisions contained in the Acts 1 and 2 Geo. III., and 5 Geo. IV., obstructed its progress, and they found it necessary to apply to government to remove them; and a bill was accordingly introduced, which would have repealed all the obnoxious clauses of the 33 Geo. II., had it not been so altered in the committee as to leave several of them in force. In 1825 the Provincial Bank of Ireland commenced business with a (nominal) capital of £2,000,000; and the Bank of Ireland has of late established branches in all the principal towns."

Since Sir Henry Parnell published the pamphlet from which we have taken the foregoing extract, several joint-stock banking companies have been founded in Ireland. The Provincial Bank, to which Sir Henry alludes, has a paid up capital of £540,000, and has been well and profitably managed. But others have been less fortunate. The Agricultural and Commercial Bank of Ireland, established in 1834, with 2170 partners, a paid-up capi-

Money. tal of £352,790, and many branches, stopped payment during the pressure in November 1836, and by doing so involved many persons in great distress. It appears to have been extremely ill-managed. The auditors appointed to examine into its affairs, reported that "Its book-keeping has been found to be so faulty, that we are convinced no accurate balance-sheet could at any time have been constructed." And they significantly added "the personal accounts at the head office require a diligent and searching revision."

The Tipperary Joint-Stock Bank, which was estab-

lished in 1839, and stopped payments in 1855, appears to have been little, if at all, better than a mere swindling engine. Luckily it did not issue notes; and the sphere of its operations was not very extensive. But, so far as its influence went, nothing could be worse, being ruinous alike to the majority of its partners and the public.

The existing Irish joint-stock banks, amounting to seven, have been all established between 1824 and 1836. We borrow principally from Thom's *Irish Almanac*, the most valuable publication of its class, the following details with respect to the Irish banks in 1856:—

Money.

ACCOUNT of the Banks existing in Ireland in 1856, their Branches, Capital, Fixed Issues, &c.

Banks.	Instituted.	Partners.	No. of Branches.	Nominal Capital.	Capital paid up.	Reserved Fund.	Fixed Issues.
Bank of Ireland	1783	...	23	£3,000,000	£3,000,000	£1,040,000	£3,738,428
*Hibernian Joint-Stock Company, Dublin	1824	604	3	1,000,000	250,000	68,000	...
Provincial Bank of Ireland	1825	945	40	2,000,000	540,000	196,787	927,667

1856	3,338,718	3,968,583	7,307,361	2,622,687

SECT. IX.—Banks of Venice, Amsterdam, &c.

It would far exceed our limits to enter into any detailed statements with respect to the banks and banking systems of foreign countries; we shall therefore confine ourselves to a brief notice of such banks as have been most celebrated, or are at present of the greatest importance.

Bank of Venice.

The Bank of Venice was the most ancient bank in Europe. Historians inform us that the republic being hard pressed for money, was obliged, upon three different occasions, in 1156, 1480, and 1510, to levy forced contributions upon the citizens, giving them in return perpetual¹ annuities at certain rates per cent. The annuities due under the forced loan of 1156, were, however, finally extinguished in the sixteenth century. And the offices for the payment of the annuities due under the other two loans having been consolidated, eventually became the Bank of Venice.² This might be effected as follows: The interest on the loan to government being paid punctually, every claim registered in the books of the office would be considered as a productive capital; and these claims, or the right of receiving the annuity accruing thereon, must soon have been transferred, by demise or cession, from one person

to another. This practice would naturally suggest to holders of stock the simple and easy method of discharging their mutual debts by transfers on the office books, and as soon as they became sensible of the advantages to be derived from this method of accounting, bank-money was invented.

The Bank of Venice was essentially a deposit bank. Though established without a capital, its bills bore at all times an agio or premium above the current money of the republic. The invasion of the French in 1797 occasioned the ruin of this establishment.

The Bank of Amsterdam was founded in 1609, on strictly commercial principles and views, and not to afford any assistance, or to commix with the finances of the State. Amsterdam was then the great entrepôt of the commerce of the world, and of course the coins of all Europe passed current in it. Many of them, however, were so worn and defaced as to reduce their general average value to about nine per cent. less than their mint value; and, in consequence, the new coins were immediately melted down and exported. The currency of the city was thus exposed to great fluctuations; and it was chiefly to remedy this inconvenience, and to fix the value or par of the current money of the country,

Bank of Amsterdam.

¹ The annuities on the forced loan of 1480, were to be suspended during periods of war.

² Cleirac, *Du Negoce, de la Banque, &c.*—(Bordeaux, 1656), pp. 112-117, a scarce and valuable volume.

Money. that the merchants of Amsterdam established a "bank," on the model of that of Venice. Its first capital was formed of Spanish ducats or ducatoons, a silver coin which Spain had struck in the war with Holland, and with which the tide of commerce had enriched the country it was formed to overthrow. The bank afterwards accepted the coins of all countries, worn or new, at their intrinsic value, and made its own bank-money payable in standard coin of the country, of full weight, deducting a "brassage" for the expense of coinage, and giving a credit on its books, or "bank-money," for the deposits.

The Bank of Amsterdam professed not to lend out any part of the specie entrusted to its keeping, but to retain in its coffers all that was inscribed on its books. In 1672, when Louis XIV. penetrated to Utrecht, almost every one who had an account with the bank demanded his deposit, and these were paid off so readily, that no suspicion could exist as to the fidelity of the administration. Many of the coins then brought forth bore marks of the conflagration which happened at the Hôtel de Ville, soon after the establishment of the bank. This good faith was maintained till about the middle of last century, when the managers secretly lent part of their bullion to the East India Company and Government. The usual "oaths of office" were taken by a religious magistracy, or rather by the magistracy of a religious community, that all was safe; and the good people of Holland believed, as an article of their creed, that every florin which circulated as bank-money, had its metallic constituent in the treasury of the bank, sealed up, and secured by oaths, honesty, and good policy. This blind confidence was dissipated in December 1790, by a declaration that the bank would retain ten per cent. of all deposits, and would return none of a less amount than 2500 florins.

Even this was submitted to and forgiven. But, four years afterwards, on the invasion of the French, the bank was obliged to declare that it had advanced to the States of Holland and West Friesland, and the East India Company, more than 10,500,000 florins, which sum they were, of course, unable to make up to their depositors, to whom, however, they assigned their claims on the States and the company. Bank-money, which previously bore an agio of five per cent., immediately fell to sixteen per cent. below current money.

This epoch marked the fall of an institution which had long enjoyed an unlimited credit, and had rendered the greatest services. The amount of treasure in the vaults of the bank, in 1775, was estimated by Mr Hope at 33,000,000 florins.¹

Bank of Hamburg. The Bank of Hamburg was established in 1619, on the model of that of Amsterdam. It is purely a deposit bank for the transfer of sums from the account of one individual to that of another. It receives no deposits in coin, but only in bullion of a certain degree of fineness. Down to 1845, it charged itself with the bullion at the rate of 442 schillings the mark, and issued it at the rate of 444 schillings, being a charge of four-ninths, or nearly one-half per cent., for its retention; but since that date, it receives and issues bullion at the same rate, charging one per mille for its expenses. It advances money on jewels to three-fourths of their value. The city is answerable for all pledges deposited with the bank: they may be sold by auction if they remain one year and six weeks without any interest being paid. If the value be not claimed within three years, it is forfeited to the poor. This bank is universally admitted to be very well managed.

SECT. X.—The Bank of France,

Money.

Bank of France.

Which is second only in magnitude and importance to the Bank of England, was originally founded in 1800, but was not placed on a solid and well defined basis till 1806. Her capital, which was originally fixed at 45,000,000 fr., was raised in the last mentioned year to 90,000,000 fr., divided into 90,000 shares or *actions*, of 1000 fr. each. Of these shares, 67,900 have passed into the hands of the public, the remaining 22,100 having been purchased up by the bank, out of her surplus profits, were subsequently cancelled. Hence her capital amounted, down to 1848, to 67,900,000 fr. (£2,716,000), with a reserve fund, first of 10,000,000 fr., and more recently of 12,980,750 fr. Since 1806 the bank has enjoyed the privilege of being the only institution in Paris entitled to issue notes payable on demand; and, as will be afterwards seen, she is now the only authorised issuer of such paper in France. Her charter and exclusive privileges have been prolonged and varied by laws passed at different periods; according to existing arrangements they are not terminable till 1897.

The bank has established, at different periods, between 1817 and 1856, offices or branches (*succursales*) in different parts of the country. They are managed nearly in the same way as the parent establishment; but their operations have been on a comparatively small scale. These are exclusive of the departmental banks united, as will be immediately seen, to the bank in 1848.

Notwithstanding the skill and caution with which her affairs have generally been conducted, the Revolution of 1848 brought the bank into a situation of extreme danger. She had to make large advances to the provisional government and the city of Paris. And these circumstances, combined with the distrust that was universally prevalent, occasioned so severe a drain upon her for gold, that to prevent the total exhaustion of her coffers, she was authorised, by a decree of the 16th March 1848, to suspend cash payments, her notes being at the same time made legal tender. But to prevent the abuse that might otherwise have taken place under the suspension, the maximum amount of her issues was fixed at 350 millions. She was then also authorised to reduce the value of her notes from 500 fr. to 200 and 100 fr.

Previously to 1848, joint-stock banks, on the model of that of Paris, and issuing notes, had been established in Lyons, Marseilles, Bordeaux, Rouen, and other large cities. And it was then determined that these banks should be incorporated with the Bank of France, and made branches of the latter. This was effected by decrees issued on the 27th April and 2d May 1848, by which the shareholders of the banks referred to (nine in number) were allowed, for every 1000 fr. nominal value of their shares, a share of 1000 fr. nominal value of the stock of the Bank of France. And, in consequence of this measure, 23,351 new shares, representing a capital of 23,351,000 fr., were added to the stock of the Bank of France, making the latter consist of 91,250,000 fr., divided into 91,250 shares. In 1851, the bank resumed, and has since continued specie payments.

The suppression of the local issues of the departmental banks was, no doubt, a judicious measure, and was indispensable, indeed, to secure the equal value of the paper circulating in different parts of the country. This, however, might have been effected by the mere stoppage of the issues of the departmental banks, without consolidating them with the Bank of France. The latter measure is one of which the policy is very questionable; and

¹ Storch, *Cours d'Economie Politique*, tom. iv. p. 102.

Money, there are, as already seen, good grounds for thinking that the banking business of the departments would have been more likely to be well conducted by local associations, than by branches of the Bank of France.

Owing to the peculiar circumstances of the last few years, occasioned partly by the war with Russia, but more by the rage for speculation and the drain for silver to the east, the Bank of France has been exposed to considerable difficulties. And in the view of strengthening her position, and also, it may be presumed, of providing a loan for government, a law has been recently passed (9th June 1857), by which the capital of the bank has been doubled. Previously to this law, her capital amounted, as already seen, to 91,250 shares of 1000 fr. each; whereas it now consists of 182,500 shares of 1000 fr. each. The new shares were assigned to the existing proprietors at the rate of 1100 fr. per share, producing a total sum of 100,370,000 fr., of which 100 millions have been lent to government at 3 per cent. Hence the measure, though it has added to the credit and security of the bank, has not made any addition to the means directly at her disposal.

Down to the passing of this law, the bank could not raise the rate of interest on loans and discounts above six per cent. But this impolitic restriction is now removed, and the bank may charge any rate of interest which she reckons expedient, except upon advances to government, the maximum interest on which is limited to 3 per cent. The bank has been farther authorised to issue notes of the value of 50 fr., to make advances on railway shares, &c., and the charter has been extended to 1897.

The bank is obliged to open a *compte courant* for any one who requires it, and performs services, for those who have such accounts, similar to those performed for their customers by the banks in London. She does not

charge any commission on current accounts, so that her only remuneration arises from the use of the money placed in her hands by the individuals whose payments she makes. It is probable, therefore, as has been alleged, that this part of her business is but little profitable. The bank also discounts bills with three signatures, at variable dates; but not having more than three months or ninety days to run. In 1855, the aggregate amount of these discounts in Paris and the departments, amounted to the very large sum of 3,262,000,000 frs., the interest being five per cent. till the 18th of October, and afterwards 6 per cent. Besides discounting bills, the bank makes advances on stocks and pledges of various kinds, and undertakes the care of valuable articles, such as plate, jewels, title-deeds, &c., at a charge of $\frac{1}{2}$ per cent. on the value of the deposit, for every period of six months and under. Nothing can show more clearly the petty retail character of the trade of Paris, and generally of France, than the smallness of the value of the bills discounted by the bank. Thus, of 963,000 bills discounted in 1847, the average amount was only £55 : 4s., and of these no fewer than 126,000 were for less than 200 frs. (£8), and 470,000 for less than 1000 frs. (£20), each! (Tooke and Newmarch *On Prices*, vi. 51.)

The administration of the bank is vested in a council of twenty-one members, viz., a governor and two sub-governors, nominated by the Emperor; and fifteen directors and three censors, nominated by the shareholders. The bank has a large surplus capital or rest. In 1855 and 1856 she divided no less than 200 and 272 fr. profits on each share; but these have much exceeded the dividends in any previous year. In 1848 the dividends only amounted to 75 frs. per share. In July 1856, the 1000 fr. share of bank-stock was worth 4075 frs.; in July 1857, it had sunk to 2880 frs. Her intimate connection with the government is decidedly the most objectionable feature in the constitution of the Bank of France.

³ Comprises 2,102,000 fr. old notes.

Money.

SECT. XI.—*Banking in the United States.*Banking
in United
States.

It has been the uniform practice of the different States of the Union to allow banks to be established for the issue of notes, payable in specie on demand. In cases where the liability of shareholders in banks was to be limited to the amount of their shares, they had, previously to 1838, to be established by Acts of the local legislatures. But, in general, these were easily obtained; and down to a comparatively late period, it may be said that banking was quite free; and that, practically, all individuals or associations might issue notes, provided they abided by the rules laid down for their guidance, and engaged to pay them when presented.

Under this system, the changes in the amount and value of the paper currency of the United States have been greater than in any other country; and it has produced an unprecedented amount of bankruptcy and ruin.

Between 1811 and 1820, about 195 banks, in different parts of the Union, became bankrupt; and it is said, in a report by the Secretary of the Treasury of the United States, dated 12th May 1820, that these failures, which mostly happened in 1814 and 1819, produced a state of distress so general and severe, that few examples of the like had then occurred.

But bad as this instance was, it was nothing to that which took place subsequently to 1834. The accounts of the aggregate issues of the banks differ a little; but the following statement is believed to be very nearly accurate, viz,—

Years.	Notes.
1830	\$66,628,898
1834	94,839,570
1835	103,692,495
1836	140,810,688
1837	149,185,890

Now observe, that this sudden and enormous increase took place under the obligation, which we are told is quite enough to prevent all abuse, of paying notes on demand. The result was, what most men of sense must have anticipated, viz., that a revulsion took place, and that every bank within the Union, without, it is believed, a single exception, stopped payment in 1837.

In 1838 such of the banks as had been best managed, and had the largest capitals, resumed payment in specie. But in 1839 and 1840, a farther crash took place. And the bank-notes afloat, which, as has been seen, amounted to \$149,185,890 in 1837, sunk to \$83,784,000 in 1842, and to \$58,563,000 in 1843. It is supposed that in this latter crash nearly 180 banks, including the Bank of the United States, were totally destroyed. And the loss occasioned, by the depreciation which it caused in the value of stocks of all kinds, and of all sorts of property, was quite enormous. And yet, vast as that loss was, it was really trifling, as a writer in the *American Almanack* has stated, compared with "the injury resulting to society from the upheaving it occasioned of the elements of social order, and the utter demoralization of men by the irresistible temptation to speculation which it afforded, ending in swindling to retain ill-gotten riches."

The evils of the American system have been aggravated by the lowness of the notes which most banks have issued. This brings them into the hands of retail traders, labourers, and others in the humbler walks of life, who always suffer severely by the failure of a bank.

Since 1838 and 1842, various measures have been taken in nearly all the States, but principally in New York, to restrain the free action of the banks, and to prevent a repetition of the calamities referred to.

In New York, for example, the banks have been divided into two great classes—the incorporated and the free banks. The former, which are incorporated by a State law, have to conform to certain regulations, and have to contribute a half per cent. annually upon their capital to a security fund, which is devoted to the payment of the notes of defaulting banks. But this is a most objectionable plan; for, in the first place, it does not prevent bankruptcies; and, in the second place, it compels the well-managed banks to contribute to a fund which goes to pay the debts of those that are mismanaged. It has consequently declined in favour, and is now rarely acted upon.

In the other, or free banking system, all individuals or associations who choose to deposit securities (minimum amount \$100,000) for their payment, are allowed to issue an equal amount of notes. And this is certainly by far the more efficient as well as the most popular of the two plans. But it is objectionable, because, 1st, A longer or shorter, but always a considerable, period necessarily elapses after a bank stops before its notes can be retired; and, 2d, Because the securities lodged for the notes are necessarily at all times of uncertain and fluctuating value; while, in periods of panic or general distrust, they become all but inconvertible. The Sub-secretary of the Treasury of the United States has animadverted as follows on this plan, in a letter dated 27th Nov. 1854:—

"The policy of many of the State governments has of late years consisted in encouraging the issue of small notes, by sanctioning the establishment of what are popularly called 'free banks,' with deposits of stocks and mortgages for the 'ultimate' security of their issues. This 'ultimate' security is, it may be admitted, better than no security at all. The mischief is, that it is least available when most wanted. The very causes which prevent the banks from redeeming their issues promptly, cause a fall in the value of the stocks and mortgages on 'the ultimate security' of which their notes have been issued. The 'ultimate security' may avail something to the broker who buys them at a discount, and can hold them for months or years; but the labouring man who has notes of these 'State security banks' in his possession, finds, when they stop payment, that 'the ultimate security' for their redemption does not prevent his losing twenty-five cents, fifty cents, or even seventy-five cents in the dollar.

"In a circulating medium we want something more than 'ultimate security.' We want also 'immediate' security; we want security that is good to-day, and will be good to-morrow, and the next day, and for ever thereafter. This security is found in gold and silver, and in these only."¹

It appears from the Report of the Superintendent of Banking for the State of New York for 1856, that the securities he then held in trust amounted to \$39,359,071, which were almost wholly lodged by banking associations and individual bankers.

During the year the securities held in trust for the under-mentioned banks that had become insolvent in 1855 were disposed of. But the sums realised by their sale did

¹ The above statements are taken from a paper read by Lord Overstone to the late Committee on Banks.

Money. not in any case suffice to pay the notes at par, while a period, varying from two to four years, would have to elapse before the affairs of the insolvent banks will be finally settled. Money.

Names of Banks that failed.	Notes redeemed.	Rates of Redemption.	Time for Redemption will expire.
Eighth Avenue Bank.....	All.....	94 cents.	May 21, 1861
Farmers' Bank, Onondaga.....	All.....	85 cents.	Nov. 12, 1859
James' Bank.....	All.....	91 cents.	June 17, 1858
Merchants and Mechanics' Bank, Oswego.....	All.....	77 cents.	Sept. 28, 1860
New Rochelle, Bank of.....	Stock notes.....	Par	June 17, 1858
New Rochelle, Bank of.....	Stock and estate notes	81 cents.	June 17, 1858

This statement sets the defective nature of the security system, as administered in New York, in the clearest point of view. It might, no doubt, be improved by increasing the proportion of securities to notes. But, owing to the variety of securities that are taken (viz., all manner of bonds and mortgages, state, canal, and railway stocks, &c. &c.), and the uncertainty of their value, a great deal of risk is always incurred in accepting them, and they can never form a proper foundation on which to issue notes.

But, however desirable, it would, we fear, be visionary to expect that local issues should be suppressed in America, or that her paper currency should be placed on a really sound foundation. But it may, nevertheless, be easily and greatly improved. And, perhaps, this would be

best effected by suppressing low notes, or those for less than twenty dollars, and increasing the proportion of securities to issues. The rules on which so much stress is laid, in most parts of America, for making the issues of banks depend on the magnitude of their capitals, or the amount of specie in their vaults, are really of no use whatever. They may be and have been eluded and defeated in a thousand ways, and serve only to make the public look for protection to what is altogether impotent and worthless for any good purpose.

The following table from Hunt's Commercial Magazine for March 1857, gives an account of the number and condition of the banks of the United States, as officially reported, in certain years from 1834 to 1856.

TABLE of the Secretary of the Treasury, showing the Number of Banks and Branches, with their Capitals, Discounts, Specie, Circulation, and Deposits, in the Union, in the following years from 1834 to 1856. The last line gives the position of the Banks near January 1, 1856:—

Years.	Banks.	Capital.	Discounts.	Specie.	Circulation	Deposits.
		Dollars.	Dollars.	Dollars.	Dollars	Dollars.
1834.....	506	200,005,944	324,119,499	26,641,753	94,839,570	75,666,986
1836.....	713	251,875,292	457,506,080	40,019,594	140,301,038	115,104,440
1837.....	788	270,772,091	525,115,702	37,915,340	149,185,890	127,397,185
1843.....	691	228,861,948	254,544,937	33,515,806	58,563,608	56,168,628
1848.....	751	204,833,175	344,476,582	46,369,765	128,500,091	103,226,177
1851.....	879	227,807,553	413,756,799	48,671,048	155,165,251	128,957,712
1854.....	1,208	301,376,071	557,397,779	59,410,253	204,689,207	188,188,744
1855.....	1,307	332,177,288	576,144,758	53,944,545	186,952,223	190,400,342
1856.....	1,398	343,874,272	634,183,280	59,314,063	195,747,950	212,705,662

Since writing the above, another crash has taken place, and all the banks in the Union, from the Gulph of Mexico to the frontiers of Canada, have again stopped payments!

This new crash affords, had that been necessary, a fresh and striking illustration of the truth of the principles we have endeavoured to establish in the course of this treatise; and it may be expected to awaken, if that be possible, the American people to a proper sense of the enormous abuses connected with their banking system; and the necessity of placing it on an entirely new foundation.

The above account shows that there had been a rapid increase of discounts since 1851, and that increase was especially great in 1856, and went on augmenting down to August last (1857). On the 8th of that month, the discounts and advances by the New York banks, amounted to \$122,077,252, the deposits in their possession being, at the same time, \$94,436,417. This was the maximum of both. On the 24th of August, the Ohio Life and Trust Company, which carried on an extensive banking business in New York, stopped payments; and

by so doing gave a severe shock to credit and confidence, which the suspension of two or three more banks turned into a panic. Notes being in a certain degree secured, the run upon the banks was principally for deposits. And to meet it they so reduced their discounts and advances, that on the 17th October, they amounted to only \$97,245,826. This sudden and violent contraction necessarily occasioned the suspension of many of those mercantile houses that had depended on the banks for discounts. And it did this without stopping the drain for deposits, which had sunk on the 17th October to \$52,894,623, being a decrease of \$41,546,784 in about two months. The universal stoppage of the banks was a consequence of these proceedings.

There seems to be no doubt that improvident advances on the part of the banks, and overtrading, were the main causes of the crisis. And it is important to observe that it is stated in the Bankers' Magazine for November 1857 (p. 430), and other works of authority published in New York, that the improvidence referred to was, in part at least, occasioned by the too high interest allowed at New York on deposits on current accounts, or at call. This

Money.

made the opulent bankers and capitalists in the Western States keep large balances at New York; and it tempted, and in some degree obliged, the bankers and money-dealers in the latter to make advances on questionable security, for the sake of the high interest payable on them. A system of this sort may be truly said to force capital into the hands of the least deserving, and to be a prolific source of wild speculation and overtrading. And whenever any serious check is given in any quarter of the Union to the process of inflation, the consequences are sure to be in the last degree disastrous: for, the greater number of the banks being very ill supplied with specie, they can resist no serious demand upon them either for payment of notes or deposits; and when one or a few stop, a panic is generated, which involves even the best managed banks in the common ruin.

A tendency to panics is, in fact, one of the peculiarities of the American system. Owing to the liability of the partners in banks being limited, the depositors in them, and the holders of notes not issued upon securities, having nothing to trust to, make all imaginable haste, when their suspicions are awakened, to save themselves by withdrawing their deposits, and cashing their notes. And hence the rapidity with which panics spread throughout the Union: and, we may add, that the slowness with which they are disseminated in this country, arises from the contrary circumstances, from the confidence placed by the public in the unlimited obligation of the partners to make good all demands.

In the city of New York, the action of the foreign exchanges compels the banks to have always on hand a very considerable amount of specie. But the reader will hardly believe with what a small stock of coin the banks in the country parts of that state, and generally throughout the Union, contrive to carry on their business. In illustration of this statement, we may mention, that in June last (1857), the fifty-six banks in the city of New York are reported in the official returns to have had \$8,000,000 notes in circulation, with an aggregate amount of no less than \$12,000,000 specie in their coffers. But at the same time that the city banks were in this situation, the circulation of the 255 country banks then existing in the state is returned at \$24,000,000, and their specie at only \$1,200,000, being only $\frac{1}{20}$ th part of their notes afloat. And as these returns give only average results, it follows that, while some of the banks would have more, others would have proportionally less specie than this medium rate.

A notion, indeed, would appear to be gaining ground among the banks, in some parts of the States, that when they have given security for their issues, they have done quite enough, and that they may dispense with the troublesome obligation to pay them on demand. It appears, for example, that in the moral and religious state of Massachusetts, there were, on the 7th July 1856, no fewer than 135 banks (excluding those in Boston), which had \$6,601,130 of deposits, and notes in circulation amounting to \$13,106,068, while their specie on hand amounted to only \$1,092,463, or about $\frac{1}{13}$ th part of the circulation. And in other parts of the Union the stock of bullion was still more scanty. Thus, in Illinois, on the 6th of July 1857, the State Bank, with notes afloat to the amount of \$725,000, had, to meet all demands, \$61,000 in specie in her coffers; while the Grayville Bank, with a circulation of \$471,556, was provided with a supply of \$18,951, in specie, and the Raleigh Bank, with a circulation amounting to \$248,000, had a specie fund of no less than \$1000! It may be supposed, perhaps, that this would be the minimum amount of specie, but no. For some banks (such as

Money.

the Bank of the Commonwealth, with notes afloat to the extent of \$84,915) were honest enough to admit that they had a considerable circulation without being encumbered with a single dollar!

It is evident that a banking system of this sort has no better foundation than a house of cards. It is sure to fall to pieces at the first touch. The grand object of by far the greater number of the bankers is to get their notes into circulation; and as these are often issued for very small sums, cost nothing, and at the same time yield some 8, 10, or 12 per cent., or more, of interest, we need not wonder at the eagerness with which they pursue this object, or at their success, or the abuses to which it leads. The discount of bills at distant dates, and their renewal, make part of the system.

The security system followed in New York, even were it generally adopted, affords no guarantee against these evils. Instead of preventing, it really tends to encourage over-issue, and it is impotent to insure a proper supply of bullion. All that it contemplates is the ultimate payment of the notes; but it does not prevent the bankruptcy of those by whom they are issued, and we have seen that it does not even accomplish that ultimate payment which it has exclusively in view. The whole system is rotten to the core; and unhappily, too, it is deeply injurious to all those with whom the Americans have any dealings, as well as to themselves.

We are glad to be able to corroborate our views of these matters by the high authority of the President of the United States. Mr. Buchanan, in his message to Congress, delivered on the 8th December 1857, makes the following conclusive statement:—"The first duty which banks owe to the public is to keep in their vaults a sufficient amount of gold and silver to insure the convertibility of their notes into coin at all times and under all circumstances. No bank ought ever to be chartered without such restrictions on its business as to secure this result. All other restrictions are comparatively vain. This is the only true touchstone—the only efficient regulator of a paper currency—the only one which can guard the public against over-issues and bank suspensions. As a collateral and eventual security it is doubtless wise, and in all cases ought to be required, that banks shall hold an amount of United States' or State securities equal to their notes in circulation, and pledged for their redemption. This, however, furnishes no adequate security against over-issues. On the contrary, it may be perverted to inflate the currency; indeed it is possible by this means to convert all the debts of the United States and State governments into bank-notes, without reference to the specie required to redeem them. However valuable these securities may be in themselves, they cannot be converted into gold and silver at the moment of pressure, as our experience teaches, in sufficient time to prevent bank suspensions and the depreciation of bank-notes."

To show the worthlessness of the returns published by the American banks, we may state that they continue, down to the latest advices (December 1857), to represent the capital of the New York banks as quite unimpaired, and as large as it had been twelve months ago! But everybody knows that it is impossible such should be the case. A very large proportion, not less, perhaps, than from a third part to a half or more of the capital of the banks, must have been lost by the late bankruptcies in that city, and by the depreciation of the stocks held by the banks.

It is truly stated by Mr. Buchanan, in the message now referred to, "that it is easy to account for our financial history for the last forty years. It has been a history of

Monflan-
quin
||
Monge.

extravagant expansions in the business of the country, followed by ruinous contractions. At successive intervals the best and most enterprising men have been tempted to their ruin by excessive bank loans of mere paper credit, exciting them to extravagant importations of foreign goods, wild speculations, and ruinous and demoralizing stock gambling. When the crisis arrives, as arrive it must, the banks can extend no relief to the people. In a vain struggle to redeem their liabilities in specie, they are compelled to contract their loans and their issues; and at last, in the hour of distress, when their assistance is most needed, they and their debtors together sink into insolvency."

We have already seen that the real value of our exports to the United States in 1856 amounted to £21,476,000. But we have been too much in the habit of estimating our commercial prosperity by the magnitude of the exports, which is a most fallacious criterion. We have heard it stated by well-informed parties, and we believe the statement to be true, that but for the extreme inflation of the banking and credit system of the United States, the imports from England during last year would not have exceeded 15 or 16 millions; and that those from France and other countries would have been reduced in something like the same proportion. And, had such been the case, production here would not have been unnaturally stimulated, and a fair profit would have been obtained from our exports, whereas they will now entail a large and most serious loss.

Besides the bankruptcy and ruin that periodically arise

MONFLANQUIN, a town of France, in the department of Lot-et-Garonne, is situated on a hill near the left bank of the Lède, 25 miles N. of Agen. The town is well built, but the streets are narrow, crooked, steep, and ill paved. Wine and fruits are produced in abundance in the neighbourhood. Pop. 5075.

MONGE, GASPARE, the inventor of descriptive geometry, was born at Beaune in 1746. He received his education at the college of the Oratory in his native town, and at a superior school in Lyons. His talent for mathematics gained for him a place as modeller at the age of nineteen in the school founded at Mézières for the instruction of engineers. From this obscure position, however, he soon raised himself by the discovery of a new and easy method of making the calculations of an operation of deployment or defiling, which had been prescribed him as a task. Bossut, who professed mathematics at Mézières, now appointed Monge his assistant; and he was attached, in the same capacity, to Abbé Nollet, professor of natural philosophy, whom he soon afterwards succeeded in that chair. In this situation he made a number of curious experiments on gas, molecular attraction, and the effects of optics and electricity, as well as refined deductions on meteorology, and on the important discovery of the production of water by the combustion of inflammable air; in which, however, he had been anticipated by Cavendish without being aware of it. About the same time Monge extended and generalized his first mathematical essays, and setting out from the principle which refers to the three rectangular co-ordinates the position of any point whatever taken in space, he made it the foundation of a new and fruitful doctrine, indispensable for all the arts of construction, and to which, when completed by successive developments, he applied the name of Descriptive Geometry. More than twenty years elapsed, however, before he succeeded in obtaining the application of his geometry to the tracings of carpentry.

from such a system, it is at all times productive of the greatest inconvenience and trouble. Where there are so many separate and independent banks (about 1400), the sphere of the influence and circulation of each is necessarily circumscribed; and when notes get to any considerable distance from the place where they are issued, especially when they get into a different State, they circulate with difficulty, and generally at a discount. But this is not the only evil by which their circulation is attended. Banks are every now and then suspending payments, or getting into discredit. And lists are regularly published of such defaulting or suspected banks, and of the rates of discount at which their notes are current, without which no traveller can leave his house, and no shopkeeper can venture to transact any business. It is truly astonishing, seeing the extreme inconvenience resulting from such a state of things, that it should be tolerated even for a week. If the general government be not sufficiently strong to suppress local issues, and to substitute in their stead a national paper issued on deposits of bullion, the public may, if they choose, rid themselves of the evil, by refusing to accept payment otherwise than in coin. The banking interest is, however, so very powerful, and embraces so great a number of individuals, that we doubt whether, even with the co-operation of the general government, the time has yet arrived for anything effectual being done for the amendment of the system. But the longer it exists, the more intolerable will it become; and in the end, no doubt, it will be suppressed. It forms, at present, the most gigantic abuse by which an intelligent people ever permitted themselves to be disgraced and oppressed. (J. R. M.)

Monge.

Through the interest of D'Alembert, Monge was received into the Academy of Sciences in 1780, and was soon after made professor of physics in the Lyceum of Paris.

Like many others, he was at first led away by the promises and hopes of the Revolution; but the terrible events that followed in such rapid succession in some measure dissipated this illusion, which he shared in common with so many others. He was made a member of the Executive Council, but resigned this irksome post in 1793. When the Committee of Public Safety made an appeal to the savans to assist in producing the *matériel* requisite for the defence of the republic, Monge applied himself wholly to these operations, and distinguished himself by his indefatigable activity. It was at this time he composed his *Art de fabriquer les Canons*, and his *Avis aux Ouvriers en Fer, sur la Fabrication de l'Acier*.

At length Monge published his *Géométrie Descriptive*, which he had so long kept secret, and which unquestionably forms his highest title to distinction. Of all the applications of which his geometry was susceptible, he has only treated of five,—viz., carpentry, stone-cutting, deployment, linear and aerial perspective, and the distribution of light and shadow. To him also France was in a great measure indebted for the establishment of the Polytechnic School. After visiting Italy on an artistic mission, Monge accompanied Napoleon to Egypt, where he was indefatigable in his scientific researches, and in his endeavours to provide for the wants of the army after the naval defeat of Aboukir.

On his return, Monge became president of the Egyptian Commission, and was again placed at the head of the Polytechnic School. On the formation of the Senate he was appointed a member of that body, with an ample provision and the title of Count of Pelusium; but on the fall of Napoleon he was deprived of all his honours. He died on the 28th of July 1818.

The separate publications of Monge are:—*Traité Elé-*

Monghir
||
Mongolia.

mentaire de Statique, Paris, 1786, in 8vo; *Description de l'Art de fabriquer les Canons*, Paris, 1795, in 4to; *Leçons de Géométrie Descriptive*, Paris, 1813, in 8vo; *Application de l'Analyse à la Géométrie des Surfaces du Premier et du Deuxième Degré*, Paris, 1809, in 4to. Monge likewise inserted four memoirs on Pure Analysis in the *Collection des Savants Etrangers de l'Académie des Sciences de Paris* (tomes vii., ix., and x.) His name also figures amongst the contributors to the *Dictionnaire de Physique* of the *Encyclopédie Méthodique*; and the *Annales de Chimie* contain several memoirs written by him. (J. B.-E.)

MONGHIR, a British district of Hindustan, in the presidency of Bengal, bounded on the N. and E. by Bhau-gulpore, on the S.W. by Ramghur and Behar, on the W. by Behar and Patna, and on the N.W. by Tirhoot. It lies between Lat. 24. 20. and 26. 1. N., and Long. 85. 40. and 86. 50. E. The district has an area of 2558 square miles, and a population estimated at 800,000. It is intersected by numerous rivers, the principal of which are the Ganges, the Sukree, the Kiyul, the Bhagmuttee, and the Gogaree. The district was acquired by the East India Company in 1765 by virtue of the firman of Shah Allum, Emperor of Delhi, granting to them the dewanny of Bengal, Behar, and Orissa. The town of Monghir is situated on the southern bank of the Ganges. It was the residence of Sultan Sujah during his government of the Bengal province, and was strengthened by him during his rebellion against his father, Shah Jehan. The fortifications have been for many years quite neglected, and the only part which remains is a small citadel, containing an arsenal and store-rooms. It is still surrounded by a wall and deep ditch, and is a place of considerable antiquity. It was an object of contention between the kings of Behar and Bengal in the early part of the sixteenth century. In 1762 it was the residence of Cossim Aly Khan, and was taken by the British the following year. The travelling distance from Calcutta is 300 miles.

MONGOLIA, an extensive district in the interior of Asia, forming part of the Chinese empire, and bounded on the N. by Siberia, E. by Mandchooria, S. by China proper, and W. by the Chinese province of Kansoo and the government of Thianshan Peloo. It lies between 38. and 52. N. Lat. and between 87. and 124. E. Long., having a length of about 1500 miles, a breadth in the central part of about 900, and an area estimated at 1,200,000 square miles. This vast territory consists of an elevated plain, bounded on the S. by the mountains of Nanshan, and on the N. by the Altai range. The centre of the plain is occupied by the Great Gobi Desert, which extends across the country from S.E. to N.W., and is estimated to contain an area of 300,000 square miles. It is covered with sand and stones, and the vegetation, except in a few oases, is very stunted and scanty. In the N., however, the surface of Mongolia becomes more mountainous, and rises in some places to a considerable height. The principal ranges in this region are offshoots from the Altai, which extend eastwards, under various names, till they reach the basin of the Amoor. On the S. the Alashan ridge, a continuation of the Nanshan, enters Mongolia, and after stretching northwards for about 400 miles, extends in an easterly direction, under the name of Inshan, for about 600 miles more. The ridge then turns north-eastwards, when it assumes the name of Khing-Khan, and continues in this direction till the Altai or Nertshinsk Mountains are reached about 120. E. Long. Its highest summit, the peak of Petscha, situated in about 43. N. Lat., is said to attain the height of 15,000 feet above the sea-level. The country which lies to the S. of the Inshan Mountains for the most part resembles in its character the Gobi Desert, and is covered with sandy hills, almost entirely destitute of vegetation and water. It is inhabited by a tribe of Mongols called Ortoos, who attend

Mongolia.

almost exclusively to the rearing of sheep, which find subsistence on the patches or oases of pasture-land that here and there occur. Of a similar nature, but less covered with sand-hills, is Kortshin, a district of Mongolia which lies to the E. of the Khing-Khan range. The country on the N.W. side of the Great Gobi is almost totally unknown. That, however, through which the caravan road to Siberia passes is said to be hilly, with level tracts of meadow land, and, though thinly wooded, is not destitute of water. There are no great rivers in Mongolia, although its table-land gives rise to many large streams which water other lands. The principal of these are the Hoangho in the S., the Kerulun and Toro, tributaries of the Amoor, on the N.E.; and the Selenga and Orchan, affluents of Lake Baikal, on the N.; besides some small streams in the interior, which lose themselves in stagnant lakes, or sink into the sand. Almost the entire extent of Mongolia is elevated more than 3000 feet above the sea, and the climate in consequence is extremely cold in winter. The weather, however, is subject to great and sudden changes, and in summer the heat is often insupportable from the want of any shelter from the rays of the sun. The principal animals of Mongolia are bears, boars, wolves, foxes, hares, wild horses, goats, cranes, quails, swans, &c. The inhabitants of Mongolia belong to that great family of races known by the name of Mongolian. They are middle-sized, strong, and muscular, with a dark-yellow complexion, broad faces, flat noses, and prominent ears. They have very little beard, and shave the hair of the head, with the exception of a single tuft. This race consists of two branches; the Proper or Eastern Mongols, who inhabit the country called Mongolia; and the Kalmucks, or Western Mongols. The former of these nations is divided into three sub-branches;—the Tshakhars, Khalkhas, and Sunnits. The first of these inhabit the country between the Gobi on the N. and the wall of China on the S.; the desert itself is occupied by the Sunnits, who are the least numerous of the three; and the Khalkhas dwell in the N. of Mongolia. They are all nomads, dwelling in tents, and pursuing pastoral occupations. Large herds of camels, horses, and sheep are reared by them, and oxen, asses, and mules by those on the frontiers of China. They are divided into twenty-six tribes, each of which is governed by a hereditary chief; with the exception of the Khalkhas, who form only one tribe, and are governed by four chiefs called *khans*. A sort of feudal system prevails in Mongolia; the princes pay a tribute to the Chinese Emperor, and the people are bound to military service between the ages of eighteen and sixty. The Chinese *Li-fanyuen*, or tribunal of foreign affairs, exercises jurisdiction over the Mongolians; and under it are one civil and two military governments. A considerable trade is carried on through Mongolia, between China and Russia, by means of caravans. The principal imports are furs, woollen stuffs, and leather; while the articles exported to Russia consist of teas, silk and cotton goods, rhubarb, sugar-candy, &c. The seat of this trade is at the towns of Kiakhta in Siberia and Mae-mae-chin in Mongolia, which are situated at a short distance from each other, on each side of the boundary between the two countries. Free intercourse is allowed between the inhabitants of the two towns during the day, but by night the gates are shut, and all communication is cut off. The trade generally continues from October till the end of winter, and is carried on solely by barter, the use of money being forbidden. Previous to the twelfth century of the Christian era, the Mongolians do not seem to have been united under one empire, or known by a common name; but under Gengis Khan, who was born in 1163, these tribes became important and received from him the name of *Kake Monghoöl*, or "Celestial People." Gengis Khan, after having raised himself, and the tribe to

Monk,
George.

which he belonged, to the head of the whole Mongolian race, conquered China, Persia, and the whole of Central Asia, and carried devastation and terror into Europe as far as the boundaries of Poland. He was succeeded by his son Oktai, under whom the empire continued to be enlarged; but it was soon afterwards split into many small tribes, which were again re-united in the fourteenth century by Timur or Tamerlane. After the death of this conqueror in 1405 the Mongol empire gradually became separated into the various tribes of which it had been originally formed. Frequent wars between the Mongolians and the Chinese took place, until the conquest of China by the Mandchourians in the seventeenth century, when the Tshakkar and Sunnit Mongols voluntarily submitted to the conquerors; and their example was followed in 1688 by the Khalkhas. It is believed that the Mongolians, who are all trained to military service, could bring into the field an army of 500,000 men; and the population of the country has been estimated, from that circumstance, at 2,000,000. (See the article ASIA.)

MONK, GEORGE, Duke of Albemarle, was a younger son of Sir Thomas Monk, and was born at Potheridge, in Devonshire, on the 6th December 1608. As his family were in decayed circumstances, he was from an early age destined to be a soldier of fortune. But before he had formed any definite plans for his future life, and before he had attained the age of seventeen, he cudgelled an under-sheriff for an affront offered to his father, and was forced to escape from punishment by volunteering into the army. His first campaign was made in that ill-concerted expedition against Cadiz, which returned inglorious at the end of the year. Nothing daunted by this unfortunate beginning, he soon afterwards sailed in the armament against the Isle of Rhé, and served as an ensign till the end of the war in 1628. The peace which followed rendered it necessary for him to earn his livelihood by entering some foreign service. He therefore embarked for the United Provinces, at that time the great seminary for soldiers, and began to devote himself earnestly to all the duties of his profession. After he had been engaged in several battles and sieges, he returned to England about his thirtieth year with the rank of captain, and with a thorough knowledge of the military art. Charles I. was then on the eve of mustering an army against his Scottish subjects. At the recommendation of the Earl of Leicester, Monk was appointed a lieutenant-colonel, and accompanied the King in those two futile expeditions which resulted in 1640 in the treaty of Ripon. The colonelcy of a regiment in Ireland was then conferred upon him by Lord Leicester, and for a year he fought with distinction against the Irish rebels. By this time the King was in the very heat of his struggle with the Parliament, and was in urgent need of the assistance of the troops in Ireland. Monk was therefore ordered to strike a truce with the rebels, and to return to England. But no sooner had he landed with his forces at Bristol in September 1643, than he was apprehended, and deprived of his command, on the charge of being friendly to the Parliament. This suspicion, founded on no other grounds than his connection with Leicester and his studied indifference to either of the contending parties, was speedily disproved, and the rank of major-general of the Irish brigade was conferred upon him as a compensation for the injury done to his character. He set out for his new regiment, then engaged in investing Nantwich, and arrived in time to be surprised and captured by Sir Thomas Fairfax in 1644. For the next two years he lay in the Tower, and his imprisonment would have been aggravated by severe poverty had not Charles I. secretly supplied him with a hundred pounds. Yet, when his royal benefactor had been left by the issues of war a hopeless captive in the hands of his enemies, Monk did not hesitate to abandon his cause. He was induced in November 1646

to purchase his freedom by taking the Solemn League and Covenant. His valour and military experience were immediately recognised by the Parliament; and in 1647 he was sent to quell the rebellion in the north of Ireland. Any other leader in this command would have become hopelessly embarrassed through the scanty supplies from England; but Monk was economical, and by his attention to agriculture, and his judicious division of the booty, managed to provide for his troops. He continued to harass and weaken the daring rebel O'Neill until 1649, when discontent and dissension among his troops forced him to patch up a truce and return to England. His talents, however, had by this time secured the confidence of Cromwell. Accordingly, in the expedition against the Scots in 1650, he was appointed lieutenant-general of the ordnance, and a regiment was raised expressly for him. He did signal service at the battle of Dunbar, was appointed commander-in-chief in Scotland, and was left by Cromwell to complete the subjugation of the kingdom. This he effected with much energy, and at the same time with much cruelty, for he butchered in cold blood the governor of Dundee and 800 of the garrison. Scotland was then formally united to the English commonwealth, and Monk returned to London in 1652. Shortly afterwards the Dutch war broke out; and in 1653 Generals Monk and Dean were sent out into the Channel in command of a fleet to encounter the redoubtable admiral Van Tromp. A fight began on the 2d of June. Dean was almost immediately shot. Monk, however, maintained the contest for two days, until the opportune arrival of a squadron under Admiral Blake gave an impulse to his attack, which in a short time scattered the Dutch ships in irretrievable flight. On the 31st of July he acted an important part in that other sea-fight which resulted in the death of Van Tromp and the humiliation of Holland. About this time an insurrection of the royalists in Scotland rendered it necessary that some able general should assume the command in that country. This post was allotted to Monk; and he repaired to the north in the early part of 1654. After reforming the discipline of the English army, which had relapsed into a state of great laxness during his absence, he followed the rebels into the Highlands. In a short time he pressed upon them so closely, that the Earl of Middleton, their principal leader, was forced to abandon his troops and to flee for his life into Holland. The rest of the insurgents soon submitted; and Monk, returning to the neighbourhood of Edinburgh, took up his abode at Dalkeith House. He now set himself to consolidate the government of the kingdom. As long as he was under the watchful and penetrating eye of Cromwell, he was prudent enough to show himself a thorough supporter of the policy and principles of the Protectorate. He set a price upon the head of all those nobles who had been up in arms for the King. He forbade the gentry to exercise any jurisdiction over their servants, to wear swords, to ride on horses of value, or to settle their own disputes. He discountenanced the Presbyterians, by depriving them of the power of excommunication and of the liberty of meeting in general assemblies. He also transmitted to London all intelligence regarding the machinations of the royalists, and took care never to intermeddle with English politics. But no sooner had Cromwell died, and left the reins of government in the feeble hands of his son Richard, than Monk changed his policy. He fixed a steady eye upon the commotions which then began to trouble the English public. He relaxed the severity of his government in Scotland, and endeavoured to conciliate both the royalists and republicans. At the same time he hoarded up money, ammunition, and arms. In 1659 the resignation of Richard, the restoration of the Long Parliament, and the consequent rupture between the Parliament and the army, opened up for Monk a way to more decisive measures. Uninfluenced by a private letter which he received at this

Monk,
George.

Monks
||
Monmouth.

period from the exiled prince, he resolved to follow that course of action which was likely to be safest, and at the same time most advantageous to himself. He therefore declared for the Parliament, and set out for London at the head of 7000 veterans. It was now apparent to all that the fate of the country was in his power, and the parliamentarians and the republicans, the two great parties into which the people were divided, alike strove to secure his aid. Yet he marched through England, hearing deputies from both, with the same cautious taciturnity, diverting their attention with fruitless negotiations, and all the while silently observing in what direction the tide of public opinion was setting. On his arrival in London he continued to fluctuate for some time between serving the Parliament and conciliating the citizens; but no sooner was he convinced that the general opinion of the nation and of his army was in favour of a freer and fuller representation of the people, than he awed the Parliament into re-admitting those of their number who had been expelled by former governments. One of the first acts of the restored members was to appoint Monk commander-in-chief of the entire forces both by sea and land. He now saw the direction in which the public mind was tending, and he now had the power to take the lead in that direction. His actions accordingly became more definite. He remodelled the army, placed several royalists in high places of command, and laid all the officers under an engagement to be completely subservient to his will. He dissolved the old Parliament and convoked a new. At length, on the 1st May 1660, he introduced Sir John Greenville to the Parliament with proposals from the King; and two days afterwards he received Charles II. on the beach of Dover. Honours and riches were now lavished upon him. He was created Earl of Torrington and Duke of Albemarle, and received several pensions. In 1664 he presided at the Admiralty; and in 1665 he was entrusted with the government of the city during the great plague. Along with Prince Rupert he commanded the fleet against the Dutch in 1666, and displayed all the courage of his youth. Monk died of dropsy on the 3d January 1670, and was buried in Westminster Abbey. (See *BRITAIN*; also *Lives of Monk* by Skinner, 1723, and by Guizot, 1849.)

MONKS. See *MONACHISM*.

MONMOUTH, JAMES, Duke of, a natural son of Charles II. and Lucy Walters, was born at Rotterdam in 1619, and was educated in France. His winning manners rendered him popular, but his foolish vanity made him the dupe of designing tacticians, who induced him to head an insurrection against his uncle James II. in June 1685. He was beheaded on the 15th July of the same year. (See *BRITAIN*.)

MONMOUTH, a parliamentary and municipal borough and market-town of England, capital of Monmouthshire, is situated at the junction of the Monnow with the Wye, 17 miles S. of Hereford, and 129 miles W. of London. The site of the town is a tongue of land formed by the junction of the two rivers aforementioned; and its vicinity is characterized by all the picturesque attractions of the valley of the Wye. The name of the town, however, is derived from the tributary of this stream—it being a corruption of Monnow's Mouth. Monmouth has been successively a British and Roman station, a Saxon fortress, and a Norman walled town. A castle was erected here during the Saxon period to overawe the surrounding district, which originally belonged to the county of Hereford, and after the Norman conquest was handed over to the custody of William Fitz-Badoron. In 1257, John, Lord of Monmouth, replaced the old fortress by one of greater dimensions; but he, having no male heirs, resigned possession in favour of Prince Edward, afterwards Edward I. Eight years later, this fortress suffered so severely from a siege by the Earl of Leicester, that it had to be rebuilt and its defences rendered more complete.

It then passed into the hands of John of Gaunt; and during the reign of his son Henry IV. became the birth-place of Henry V., the hero of Agincourt. In 1846 the castle, being held by the royalists, was besieged and taken by the parliamentary forces. Only a few ruins remain of this ancient building. Traces of the old town wall and moat are also apparent, and one of the four city gates is still entire. The town is provided with an excellent market-place, and contains several other objects of note and interest. The assize court buildings, the façade of which is decorated with a statue of Henry V., the castellated county jail, and St Mary's church, are the most prominent buildings. The latter occupies the site of a church belonging to a Benedictine priory once situated here, and is remarkable for the beauty of its spire, which is 200 feet in height. St Thomas's church, on the other side of the Monnow, an old building, partly in the Norman, partly in a later style; a handsome town-hall; and Jones's Free Grammar School, are the only other edifices worthy of mention. The borough was incorporated by Edward VI. in 1550, and also received charters from Queen Mary in 1557, James I. in 1606, and Charles II. in 1666. It is governed by a mayor, 4 aldermen, and 12 councillors; and unites with Newport and Usk in returning a member to Parliament. Monmouth owes most of its prosperity to the periodical influx of persons during the assizes and sessions, and to the large number of tourists attracted by the beauties of the district. Manufactures are few and insignificant; but a considerable trade in timber and metals is carried on; while the Wye fisheries give employment to several persons in the town and vicinity. A market is held on Saturday. Pop. (1851) 5710.

MONMOUTHSHIRE, a maritime county of England, bordering on South Wales, is bounded on the N. and N.E. by Hereford, N.W. by Brecknock, E. by Gloucester, S. by the estuary of the Severn and the Bristol Channel, and W. by Glamorgan. It is 34 miles in length from E. to W., by 28 miles in greatest breadth, and contains an area of 368,399 statute acres. The coast line, which is 20 miles long, extends from the Rumney to the Wye, and includes the two harbours of Chepstow and Newport. These are respectively formed by the mouths of the rivers Wye and Usk, which here debouch into the Bristol Channel. The scenery of Monmouthshire is highly picturesque and varied, uniting the beauty of Devon with the grandeur of Wales. The language spoken is partly Welsh, partly English. The latter is the ordinary language of the districts abutting on Gloucestershire and Herefordshire, and Welsh of the rest; though, owing to the establishment of schools, there are now few persons who do not understand both languages, especially in the towns. The Welsh spoken is the Gwentian, one of three dialects prevalent in Wales.

Monmouthshire has an irregular surface, encircled by a chain of heights, some of which attain the altitude of mountains. This ridge commences near Wentwood Forest on the south-east, and extends to the neighbourhood of Newport on the south-west. The sea-shore, however, is skirted by two extensive levels, called Caldecot and Wenloog levels, protected from the sea by strong embankments, which are kept in repair by the landowners of the district. The geological structure of the county is interesting. Devonian rocks prevail east of a line drawn between Abergavenny and Newport, and is pierced by an under-stratum of Silurian near Usk, in the centre of the county; while the South Wales coal-field occupies the western half of the county, and becomes rich in iron as well as coal in the vale of Crickhowell, on its north-west border. The coal measures are skirted by a narrow strip of carboniferous limestone—useful as a flux with iron ore, as well as for building and manure. A tongue of carboniferous limestone also enters the county at Chepstow from the Dean Forest coal-field, and is bor-

Monmouth-
shire.

Monmouth-
shire. dered on the south by a strip of Permian formation, which forms the Monmouthshire shore of the Severn.

The surface in the southern or maritime district of the county consists of large tracts of moorland, having a rich, loamy soil, which occasionally is highly favourable to the growth of trees. In the east the soil is of a reddish colour, which, when carefully cultivated, is very productive, and this district extends along both sides of the River Usk. The soil of the western and most mountainous parts, on the other hand, is generally thin and peaty, and covers strata of sandstone, under which the coal and iron are found.

Agriculture is comparatively backward in Monmouthshire; the farms are small, ranging from 20 to 100 acres, and are held almost universally from year to year. The farm buildings are likewise inferior, though quite equal to the capabilities of the present class of tenantry. The produce of wheat averages 20 bushels an acre; and, where skill has been applied, as many as 35 bushels have been obtained. The soil resting on the red sandstone, when kept clean and drained, is here admirably adapted for the growth of wheat; but the crop is taken too often. Many farms where barley is raised, being unweeded and undrained, produce no more than 10 to 15 bushels an acre of that cereal, but, with better cultivation, would yield twice the quantity. Nor are the green crops very luxuriant, owing to the general want of drainage—although on some estates 20 tons per acre of Belgian carrots, and 40 tons per acre of mangel-wurzel, have been produced. Efforts are being made by the landlords to stimulate improvement; and the Duke of Beaufort, the owner of a large part of the county, has shown that, by skill and management, good crops may be obtained from the worst land. One of the results of this recent interest taken in agriculture is the adoption by many farmers of the light fences in place of the old-fashioned jungles, which, however much they add to the picturesque, diminish the breadth of land and injure the crops. The county contains many dairy farms, for which cows of the Durham and Gloucester breeds are preferred. Hereford cattle are common; and the Radnor breeds improve wonderfully on the pastures here. Of sheep, the prevalent breeds are Ryelands and Leicesters, and a smaller number of South Downs. The rearing of mules is carried on perhaps to a greater extent than in any other county, and Spanish asses are imported for the purpose. The animals produced are well-formed and capable of bearing great fatigue. They are employed in carrying coal on their backs in the more hilly districts.

Monmouthshire, however, is a mining rather than an agricultural county, and the chief commerce flows from its staple productions—coal and iron. There are twelve beds of the former, which vary in thickness from 3 to 9 feet. The area of the Monmouthshire coal-field is about 90,000 acres; the seams which can be profitably wrought averaging a thickness of 50 feet, and the yield being nearly 73,000 tons an acre. The principal seams lie at a considerable depth below the ground, and they are reached by digging what are called in this country “levels,” which are passages driven through the sides of the hills, instead of perpendicular shafts. The quantity of coal exported from Newport in the year 1856 was 681,442 tons; and, in addition, a large quantity was carried into the interior of the country by railway, or found an outlet at the port of Cardiff, in the neighbouring county of Glamorgan. The ironstone of Monmouth occurs both in beds and in large detached masses, and yields from 18 to 55 per cent. of iron. The ore is the common clay-ironstone. The iron-works are situated in the neighbourhood of Pontypool, which is perhaps one of the first places in which iron was fabricated in this kingdom. A family named Grant were the first ironmakers at Pontypool. They were succeeded about the year 1565 by Mr Richard Hanbury, citizen and goldsmith of London,

who held a third part of the immense tract of mineral property in the neighbourhood at a rental of 3s. 4d. a year, the whole of it having been let by the owner, the Earl of Abergavenny, for 9s. 4d. only. Mr Hanbury greatly increased the works; and they were extended still more by his grandson, Mr Capel Hanbury, the first great ironmaster of his age. At that time (the reign of Elizabeth) the ore was smelted with charcoal; and to prevent the destruction of timber in making it, a statute was passed prohibiting the erection of iron-works except in certain districts; of these Monmouthshire was one. Yet in 1740, nearly 150 years afterwards, when coal was first successfully employed in iron-smelting, Monmouthshire contained only two iron furnaces, making 900 tons annually; while the invention of the steam-engine in 1788 only led to the erection of a third furnace, by which the “make” was increased to 2100 tons. In 1790, however, three new furnaces were erected at Blaenavon, and others at Blaendare and Ebbw Vale. Five years later the Nantyglo works were commenced, but at first did not succeed, and were suspended for a year. Under the management of the Bailey family, however, they have now come to be ranked among the greatest works of the kind in the United Kingdom. A great impulse was given to the Monmouth iron trade by the success of that of Blaenavon, and a perfect range of furnaces sprung up along the valleys that run towards Merthyr-Tydvil. In 1803, the Beaufort, Ebbw Vale, Clydach, and Varteg works were put in operation; then followed the Tredegar in 1805, the Nantyglo in 1811, the Coalbrook Dale in 1821, the Blaina in 1824, the Pentewan in 1825, the Abersychan in 1827, the Bute in 1828, the Golynos, afterwards united with Pentewan, in 1837, and the Victoria works in 1838. These are all very extensive furnaces; but there are besides many minor works, some of which have been recently opened. The South Wales system of iron-works commence at Clydach, 4 miles from Abergavenny, and extend in an unbroken line to Merthyr, a distance of 20 miles. The Monmouthshire coal and iron trade is greatly facilitated by a succession of valleys, with a gradual inclination towards Newport, whence the produce is exported.

A group of mountains in the north, neighbouring on Abergavenny, called the Bloreng, or Grayridge, possesses great beauty of outline. The northern extremity of the chain is 1720 feet high; while its loftiest peaks, the Sugar-Loaf and Holy Mountain, are respectively 1856 and 1498 feet high.

The chief rivers of the county are the Wye, the Monnow, the Usk, the Rumney, and the Ebbw. The first is universally pronounced one of the most beautiful of the English rivers, meandering, as it does, through a rich as well as picturesque country, its banks overhung with trees, and occasionally darkened by some abrupt and lofty cliff. Rising from the sides of Plynlimmon in Montgomery, the Wye separates Brecknock from Radnor, and enters Hereford, which it traverses in a S.E. direction, till it forms the boundary between that county and Gloucester. It then takes a southerly course, dividing the counties of Monmouth and Gloucester; and after passing the towns of Monmouth and Chepstow, enters the Bristol Channel, after a course of 40 miles through the county. The river is navigable at the town of Monmouth, and is used for the export of timber and bark. The Monnow rises at Hay in Herefordshire, enters Monmouthshire near Langua bridge, and forms the eastern boundary of the county, flowing through a beautiful valley until it joins the Wye at Monmouth. The Usk enters the county from Brecknock near Abergavenny, becomes tidal at Caerleon, and falls into the sea a little below the port of Newport. The Rumney rises in Brecknock, forms the boundary between that county and Monmouth, and after a meandering course southwards, enters the Bristol Channel 2 miles E. of

Monmouth-
shire.

Monmouth-
shire.

Cardiff. The Ebbw finds its source at Ebbw Vale, on the N.E. of the county, and after a southerly course enters the estuary of the Usk. There are also some minor streams: the Sirrhw, a feeder of the Ebbw; the Avon, of the Usk; the Trothy, of the Wye; and the Honday, of the Monnow. Of these streams, the Wye and Usk are the most abundant in salmon; while all the rivers are well stocked with trout and other fish. The fishermen here use boats called *coracles*, said to be of the same character as those in use among the ancient Britons. They are made of thin hoops, covered with strong canvas, thickly coated with pitch, and edged with basket-work. The seat is in the middle of the coracle, which measures about 5 feet in length, and is light enough to enable the fisher to carry it on his shoulders. Great dexterity and caution are required to avoid upsetting, for even the slightest movement in hooking a fish will be sufficient to overturn the craft.

The means of internal communication in Monmouthshire is rendered complete by the number of railways and canals which intersect it. The South Wales line, connecting London and Milford Haven, is carried along the coast of this county, and passes by Chepstow and Newport. The Newport and Abergavenny Railroad, which unites with the Hereford line, connects Monmouthshire with Shrewsbury and the north. A branch from the same also passes through Pontypool to Blaenavon, and a number of short mineral lines bring the various coal and iron stations into ready communication with the sea and the main railroads.

The population of the county has shown a steady increase for the last fifty years, and the only subject for remark is the preponderance of males over females. In 1831 there were 112,686 inhabitants; in 1841, 157,021; and in 1851, 177,130. Of the last sum 92,301 were males, and 84,829 females. The county contained in 1851 only three towns having more than 5000 inhabitants,—viz., Newport, 19,323; Tredegar, 8305; and Monmouth, 5710. Monmouthshire returns three members to Parliament,—two for the county and one for the combined boroughs. It is divided into 6 unions and 161 parishes, which afforded in the half-year ending Lady-Day 1857, poor-relief to the amount of £19,210, or £710 less than what was expended in the former half-year. The county is included in the Oxford circuit, and belongs to the diocese of Llandaff, with the exception of three parishes, which pertain to that of Hereford, and three to St David's. In 1851 there were 434 churches in Monmouth, of which number 159 belonged to the Established Church, 126 to the Methodists, 79 to the Baptists, 51 to the Congregationalists, 8 to the Roman Catholics, and 6 to the Mormons. Education was dispensed, at the same date, in 336 day schools, 135 of which were public, attended by 12,632 scholars, and 201 private, attended by 4548 scholars; and also in 330 Sunday schools, attended by 28,882 scholars. The number and character of the literary institutions, with their respective libraries, in 1851, are too insignificant to require notice.

The history of Monmouthshire can be carried back to the time of the Roman conquest. It formed a part of the territory belonging to a native tribe called the Silures, at the time of the second Roman invasion of Britain. Ostorius Scapula, one of the commanders of the Emperor Claudius, attempted to expel them, but the Silures, assisted by the mountainous character of the district, ultimately obliged him to retire. The general died not long afterwards of an illness caused by the fatigues of his campaign. Julius Frontinus was, however, more successful in the reign of Vespasian, and Monmouthshire became a part of *Britannia Secunda*,—a term applied to the conquered territory west of the Severn. After the Romans evacuated Britain A.D. 408, South Wales was divided into a number of petty states, which were either at war with each other or engaged in repelling the attacks of the Scots and Picts. Vorti-

Monmouth-
shire.

gern, who invited the Saxons over to Britain to expel these ruthless bands, was a king of Gwent, as Monmouthshire was anciently called. For many years after, the Angles and Welsh were at constant war, until the latter were forced to submit. In 1034 the territory of Gwent or Monmouth was invaded by Canute the Dane, and several fortresses were occupied by his forces. It remained in the possession of the English till the Norman conquest, when William, unable to spare sufficient troops to subdue the district thoroughly, incited his barons to make incursions at their own cost. The lands which they conquered became their own, and were held *per baroniam*, with the right of administering justice upon them. The subsequent history of the county exhibits a series of struggles between the possessors of the land and the Welsh. The natives were then little better than barbarians, and hated the English, who held their towns and castles, punished their bards as vagabonds, and excluded them from every public office. Henry II. seized and garrisoned the town and castle of Caerleon in 1174, when on his way to conquer Ireland. Henry III. defeated Llewellyn, the Welsh prince, at Grosmont Castle, and twice seized that fortress, giving it at first to Hubert de Burgh, but afterwards annexed it to the duchy of Lancaster. Henry V., when Prince of Wales, in 1405 drove Owen Glendwr, the last of the Welsh chieftains, out of Grosmont Castle, and defeated him in battle at Usk. During the Parliamentary war Monmouthshire became again a field of contest. Raglan Castle, a favourite residence of Charles I., was held for him in 1646 by Henry, Marquis of Worcester, who, although then eighty-five years of age, kept up the defence for two months, after which he capitulated to Fairfax. Chepstow Castle surrendered to the parliamentary forces two years later, being the last fortress which defied the power of Cromwell. The feudal jurisdiction, which was abolished by Henry VIII. in 1535, was succeeded by an administrative arrangement, which placed Monmouth among the English shires; and it was regularly considered an English county in the reign of Charles II., when it was included in the Oxford circuit. The last vestiges of the baronial system, however, were not got rid of until the reign of William III., when the Lord Marchers' Court, held at Ludlow, Shropshire, was suppressed by act of Parliament on the petition of the Welsh people.

Monmouthshire is rich in antiquarian remains. It contained five Roman stations,—*Venta Silurum*, now Caerwent; *Isca Silurum*, now Caerleon; *Gobannium*, now Abergavenny; *Blestium* and *Burrium*;—the last two are doubtfully fixed at Monmouth and Usk. The remains of walls, aqueducts, subterranean buildings, mounds, and pavements, are remarkable. The county was traversed by two Roman roads,—the Via Julia, leading from the mouth of the Severn to Caerwent, Caerleon, and onward towards Neath; and the Akeman Street, from Caerwent, across the Wye and Severn, to Cirencester. The former can still be traced, and is called in the Gwentian dialect *Sarn-her*, "the long-paved causeway." There are traces of six British and Roman encampments, and remains of no less than twenty-five Norman fortresses: these formed two lines, the first, including Scenfreth, Grosmont, Monmouth, Chepstow, and Caldecot, on the banks of the Monnow, the Wye, and the Severn; and the second, including White Castle, Usk, Langibby, Caerleon, and Newport, stretching in a diagonal line from Grosmont to the banks of the Rumney. At the time of the Reformation there were two hospitals and fifteen other religious houses in the county; but two only remain—Llanthony and Tintern abbeys—both in ruins. The former was once a distinguished priory of Cistercians, and, judging from the remains, never had been a highly-ornamented building. It was erected about 1112, but was soon afterwards abandoned by its inmates. Tintern Abbey, famous

Monochord alike for the beauty of its architecture and of the surrounding scenery, was founded in 1131, and dedicated to St Mary. The ruin, which exhibits the purest Gothic style, is roofless, but the walls are almost entire, and some of the piers are still standing. (F. C.)

Monomoise.

MONOCHORD, an instrument by which the several proportions of musical sounds and intervals, as well in the natural as in the tempered scales, are tried. Originally it had, as its name implies, only one string; but it is better constructed with two; for, by means of the additional string, an opportunity is afforded of judging of the harmony of two tempered notes in every possible variety of temperament. The monochord is called the harmonical canon. Its invention is ascribed to Pythagoras.

MONOGRAM, an abbreviation of a name by means of a character or cipher, formed by the interweaving of two or more letters with each other. They are of very ancient date, and were employed upon coins, medals, seals, &c., by not a few of the more distinguished families of Greece and Rome. They were not used by the Roman emperors till a later period. The Greek monogram for the name of Christ **Χ**, consisting of a combination of the first two

letters of *Χριστος*, is found on the coins of Constantine the Great; and was continued by not a few of his successors. Monograms appear frequently on coins, &c., during the middle ages, and they were frequently employed by princes (e.g., the kings of France, A.D. 751–987), and other dignitaries of that period, as a substitute for their signature. This mode of adhibiting their names to their works was frequently adopted in later times by printers, painters, and engravers; and monograms are occasionally to be met with at the present day attached to books and works of art. When all the letters which compose the word are expressed in the monogram, it is called *perfect*; otherwise it is said to be *imperfect*.

Much labour and research have been expended on the deciphering of ancient monograms, and many of them remain still unintelligible. The most valuable works on this branch of the subject are Montfaucon, *Palæographia Græca*; Froelich, *Annal. Reg. Syr.*; Combe, *Museum Hunterianum*; Torremuzza, *Description des Monnaies de Sicile*; Pellerin, *Recueil des Villes, des Peuples, et des Rois*; Mionnet, *Traité de la Numismatique*; Le Blanc, *Traité Historique des Monnaies de France*. Of later monograms various treatises have taken notice; but the ablest works, since the Abbé de Marolles, in 1667, drew attention to the subject, are those of Bartsch, *Peintregraveur*; and especially Brulliot, *Dictionnaire des Monogrammes*, &c., 2 vols. 4to, Munich, 1832–34,—both works of great accuracy and research. (See **NUMISMATICS**.)

MONOMANIA. See **MENTAL DISEASES**.

MONOMOISE, or **MONOMOEZI**, a territory of southern Central Africa, situated on the eastern shore of Lake Taganyka, inclosed by no definite boundaries, but having an estimated length of 570 miles, by a breadth of 420 miles. S. Lat. (of Oha the capital) 6. 34, and E. Long. 29. It is now two centuries and a half since this country was first heard of by Europeans, and at that time it was believed to extend from Abyssinia in the N., to Monomotapa in the S., and from the E. coast far into the interior of Central Africa. From more recent explorations, however, its limits are found to be not nearly so extensive, and its exact position has been now determined by Lake Taganyka instead of Lake Nyassa, on whose shores some later geographers have incorrectly placed it. Monomoise, which may be said to lie between 3. and 7. of S. Lat., occupies an elevated tableland watered by the Luffia and its affluent the Magrassie, and is composed of several tribal districts. These are stated by one authority to amount to six,—viz., Uranga, Ovinza, Ugilye, Oha, Usooie, and Oocanga; while according to a later

account, they are said to number only four. Each tribe is governed by a chieftain, who pays homage to the great chief of the Oha tribe, and thus the entire territory has sometimes been designated the Empire of Monomoise. The prefix *mono* signifies great, or master; hence the full name is equivalent to *the great Moises*, or the chief nation of the Moises; and it is known that this last name is borne by a numerous people, widely scattered over the interior, and divided into various tribes. The Monomoises are a ta. race, and those residing on the shores of the lake are said to be as fair as the Abyssinians. In civilization they surpass nearly all the other South African nations, and are described as industrious and ingenious, as well as hospitable to strangers. Their dress consists of cotton, manufactured by themselves, and which they make not only for their own use, but also for transmission to the sea-coast for shipment. Trade, which is largely engaged in, is much furthered by the use of a hardy breed of asses for conveying goods to the sea. The Monomoises, however, are far from a peaceful people; on the contrary, they are said to be at constant war with their neighbours in the interior, though friendly relations are generally preserved with the commercial tribes of the coast. Large caravans proceed annually from Oha to Zanzibar, conveying cotton, copper, ivory, and a sort of red oil, which articles are obtained from the country to the S.W. of the lake. These generally start for the coast in March or April, after the end of the rainy season, and return after an absence of nine or ten months. Lake Taganyka contains large quantities of fish, has numerous islands, and is navigated by long and narrow boats without sails. Its breadth at the town of Oha, situated on its shores, is about 24 miles; its depth is also great, and it is frequently agitated by a considerable swell. The River Luffia, which waters the Monomoise country, flows from Lake Taganyka, and is joined by several tributaries. No estimate has as yet been made of the population, but it is said to be large, especially on the shores of the lake.

MONOMOTAPA, a country in the S.E. of Africa, to the S. of the Zambesi, between 15. and 19. S. Lat., and 30. and 35. E. Long. It is inhabited by a people of the Mucarang race, and was formerly an important empire, but it is now split up into independent states, of which the most important are Susas and the Katalosas. The name Monomotapa is not now in use.

MONOPHYSITES, a body of heretics who adopted the doctrine of Eutyches the Archimandrite, the opponent of Nestorius. (See **EUTYCHES**.) The latter, from the two natures of Christ, inferred also two persons,—a human and a divine. Eutyches, on the other hand, from the one person inferred also one nature, viz., the Divine,—the human having been absorbed into it; but in the end his own united with the rival heresy in more points than one. After the condemnation of Eutyches at Chalcedon, his heresy became divided into ten chief sects, whence it has received the name of the “ten-horned.” Of these the principal leaders, as enumerated by Anastasius the Sinaite, were Eutyches himself, Dioscorus, Timothy Celurus, or “the Cat,” Gajan, Julian, Severus, Peter “the Fuller,” Barsanuphius, Theodosius, and Jacob Baradaeus, or “the Ragged.” Besides these, are to be enumerated the followers of Peter “the Stammerer,” the Acephali, the Aphthartodocetæ, who held that Christ’s body was in itself incorruptible, and not subject to passion or suffering; the Theopaschites, from Peter “the Fuller,” who held that the Godhead suffered directly; and the Theodosians, from Severus and Theodosius of Alexandria, whose followers soon fell into numberless divisions. The chief of these were the Agnoetæ, whose distinctive tenet it was, that Christ was altogether ignorant of things to come; and the Tritheites, who thought that there were three essences as well as three persons in the Godhead. There were also numberless other sects who differed

Monomu.

sites.

Monopoli
||
Monothelites.

from each other on points of more or less consequence, and agreed only in their hatred of the Council of Chalcedon, and the doctrine it laid down.

When all attempts of the imperial power to restore peace to the churches of Egypt and the East had failed, the Emperor Zeno, in the year 482, published his "Henoticon," by which he hoped to put a period to the disturbances which on more than one occasion had terminated in open riot and bloodshed. The "Henoticon" asserted the Creed of the General Council of Nice held in 325, and anathematized Nestorius and Eutyches, but said nothing positively as to Monophysitism in itself,—that is, the doctrine of the nature or natures after the Incarnation. The greater number of eastern bishops readily signed this formula; but Leo the Great, then Pope, separated them in consequence from the communion of the Church of the West; while the more obstinate of the Monophysites seceded from the rule of their bishops, and formed the sect of the Acephali, which existed upwards of three centuries, when its members were received again into the church.

The Monophysites still exist in Egypt and the East, under the title of Jacobites, which they derived from Jacob Baradaeus; whilst the orthodox are distinguished by that of Melchites, or Royalists, from their adherence to the edict of the Emperor Marcian, in favour of the Council of Chalcedon, and their adoption of its doctrine. (G. J. D.)

MONOPOLI, a town of South Italy, Naples, province of Bari, and on the shore of the Adriatic, 26 miles S.E. of the town of Bari. It stands on an eminence overlooking the sea, and is protected by a castle. The streets, which are narrow and irregular, are rather gloomy in appearance, from the height of the houses. The town, nevertheless, is the favourite resort of many people of wealth. There are numerous churches; and the cathedral, which is a handsome edifice, contains a painting of "St Sebastian" by Palma Vecchio. There are two suburbs, in which the houses are better built than in the town itself. Manufactures of linen and cotton fabrics are carried on; and there is a considerable trade in wine and oil, as well as in the manufactures of the place. The town has two harbours, which, however, though deep, are not well sheltered. On the coast, about 6 miles S.E. of Monopoli, stand the ruins of the ancient *Gnatia*, known in modern times by the name of Torre d'Egnazia. Monopoli is the seat of a bishop, who is a suffragan of the Holy See. Pop. 15,000.

MONOTHELITES, a heretical offshoot from the sects of the Apollinarians and Monophysites. They distinguished the will from the operation, and said that a multiplicity of wills must of necessity involve a multiplicity of willers. In order, therefore, to preserve the unity of Christ's person and nature after the Incarnation, they held that in Him there was one will or energy only. This will was not human, for that would infer strife and sin; but they admitted Him to be perfectly sinless, and hence they ascribed to Him a divinely human will, which, from a term used by Dionysius the Areopagite, they called *Theandric*. As the Eutychians absorbed the human in the Divine nature, so the Monothelites merged the human will in the Divine. Their opponents met them by the denial of their major premiss, that the will depends on the *person* of the willer, and asserted, on the contrary, that it is the result of the nature; and, therefore, that in Christ each nature had its own manner of operation and will, though in Him these wills were in no degree in sinful opposition.

Monothelitism was first heard of in the seventh century, and was in its vigour from the year A.D. 629 to the sixth general council held A.D. 680. Heraclius, the Greek emperor, was the original cause of its formal enunciation. After he had recovered the provinces rent from the empire by the Persians, he was desirous of strengthening his power by the reunion with the dominant church of those Nesto-

Monothelites.

rians who had been driven into Persia. The leaders of the Monophysites acceded to his wish, on the condition of its being ruled, that after the union of the two natures in Christ, there was but one mode of operation and will; Sergius, the Monophysite patriarch of Constantinople, agreed; and Honorius, in consequence, published in the year 630 an edict in favour of that doctrine. On this Cyrus, who had been recently converted to Monothelitism by Sergius, and promoted by Honorius to the patriarchate of Alexandria, held a council in that city A.D. 633, and propounded nine articles of faith, which at first met with great success. He was earnestly opposed, however, by Sophronius, a monk of Palestine, then residing at Alexandria, who, on being made patriarch of Jerusalem, assembled a council there and condemned the Monothelites. Sergius thereupon wrote to Pope Honorius, who in reply expressed his approbation of the doctrine of Sergius as opposed to that of Sophronius, and clearly enunciated Monothelite doctrine. "We confess," he said, "one will in Jesus Christ, because the God-head took not our sin, but our nature as it was created before the corruption of sin."

More than one of the Romish controversialists have made unsuccessful attempts to defend the reputation of Honorius from the accusation of heresy arising out of his letters to Sergius. The error of his Holiness, like that of the Monothelites, lay in the assumption that two wills could not co-exist in our Lord without sinful opposition; and hence he must be ranked with those heretics with whom he was subsequently condemned in the sixth general council.

To put an end to the dispute, Heraclius, in the year 639, issued the edict known by the name of the "Ecthesis," or exposition of the faith, in which he laid down the doctrine of one will, but prohibited all controversy on the question of one or two operations. Many eastern bishops, with Pyrrhus, the successor of Sergius, at their head, received the "Ecthesis;" but John IV. of Rome immediately assembled a council in that city, in which the "Ecthesis" was rejected, and the Monothelites condemned. The most able opponent of Monothelitism at this time was Maximus the monk, who vanquished Pyrrhus, Patriarch of Constantinople, in a public disputation. Theodore of Pharan, in Arabia, was the most prominent of its champions.

In the year 648, Constans the Emperor revoked the "Ecthesis," and published in its place a formula known by the name of the "Type," which was formally condemned by Pope Martin I. in the Lateran Council of 649. Constans, enraged at what he supposed an attack on his authority, caused Martin to be seized and carried to the Isle of Naxos, where he was kept prisoner for a year. Thence he was removed to the town of Chersonesus in the Crimea, where he soon afterwards died. Maximus was next arrested and brought, with his disciple Anastasius, to Constantinople. On his refusing to adopt Monothelitism in any guise, he was forcibly conveyed to Byzra in Thrace; thence he was carried back to Constantinople, where he was publicly scourged, had his tongue cut out, and his right hand severed at the wrist. After this he was banished to Lazi in Colchis, where he soon died. The West, overawed by these violences, remained for some time quiet; but in the year 677 the schism between the East and West was complete. To put a final termination to these disputes, the sixth Œcumenical Council was assembled at Constantinople in A.D. 680, at which the Emperor was present in person. The result was to establish the doctrine of two wills and operations; and the Monothelites, with Pope Honorius at their head, were again formally condemned. The doctrine of Monothelitism was henceforth confined to the people inhabiting Mounts Libanus and Antilibanus, who are known in history by the name of Maronites. (See MARONITES.) (For more detailed information respecting the Monothelites, consult Neander's *Church History*, vol. v.) (G. J. D.)

Monro
||
Monroe.

MONRO, ALEXANDER, a celebrated physician and anatomist, and founder of the medical school of Edinburgh, was the son of John Monro, a surgeon in Edinburgh, and was born in London in 1697. He showed an early inclination to the study of physic; and his father, after giving him the best education which Edinburgh then afforded, sent him successively to London, Paris, and Leyden, to improve himself further in his profession. On his return to Edinburgh in the autumn of 1719, he was prevailed upon to read some public lectures on anatomy, and to illustrate them by showing the curious anatomical preparations which he had made and sent home when abroad. He at the same time persuaded Dr Alston, then a young man, to give some public lectures on botany. Accordingly, in the beginning of the winter of 1720, these two young professors began to give regular courses of lectures,—the one on the *materia medica* and botany, the other on anatomy and surgery. These were the first regular courses of lectures on any of the branches of medicine which had ever been read at Edinburgh, and may be looked upon as the opening of that medical school which has since acquired so great reputation all over Europe.

On the foundation of the medical faculty of Edinburgh in 1721, Dr Monro was appointed university professor of anatomy, but was not received into the university till the year 1725, when he was inducted along with Maclaurin, the celebrated mathematician. From this time he regularly gave a course of lectures on anatomy and surgery from October to May, upon a most judicious and comprehensive plan,—a task in which he persevered with the greatest assiduity, and without the least interruption, for nearly forty years; and so great was the reputation he had acquired, that students flocked to him from the most distant corners of his Majesty's dominions. Dr Monro had a principal share in founding the Royal Infirmary of Edinburgh, and was accustomed occasionally to give lectures on the surgical cases which occurred there.

In 1759 he entirely relinquished the business of the anatomical theatre to his son Dr Alexander Monro, who had returned from abroad, and had assisted him in the course of lectures delivered the preceding year. He still endeavoured, however, to render his labours useful, by reading clinical lectures at the hospital for the improvement of the students. Dr Monro died on the 10th of July 1767, in the seventieth year of his age.

Of his works, the first in order is his *Osteology, or Treatise on the Anatomy of the Bones*, which appeared in 1726, and was translated into most of the languages of Europe. In the later edition he added a description of the *Lacteal Sac* and *Thoracic Duct*, and gave an admirable description of the *Anatomy of the Nerves*. The six volumes of *Medical Essays and Observations*, so well known and so much esteemed, were published by a society in Edinburgh, and were mainly owing to his zeal and activity. In the first two volumes of the *Physical and Literary Essays*, published by the Physical Society of Edinburgh, we find several papers written by him, possessing very great merit. His account of the *Success of Inoculation in Scotland* may be considered as his last publication. A collection of his works, properly arranged, corrected and illustrated with copperplates, with a Life of the author prefixed, was published by his son, Dr Alexander Monro, in one 4to volume, Edinburgh, 1781.

MONROE, JAMES, a President of the United States, was descended from a Scottish family, and was born in Westmoreland county, Virginia, in April 1758. After receiving his education at William and Mary College, he entered the revolutionary army in 1776, was engaged in several battles, and rose to be aide-de-camp to Lord Stirling, with the rank of major. Towards the close of the war General Washington conferred upon him the rank of colonel; but as he was unable to raise an army in Virginia, already ex-

hausted by former conscriptions, he devoted himself to the study of law. His sagacity, firmness of purpose, and plodding perseverance soon marked him out as one adapted for civil offices. He was elected a member of the Assembly of his native state in 1782, a member of the old Congress in 1783, a member of the Virginia Convention in 1788, and a senator of the United States in 1790. In 1794 he was appointed minister plenipotentiary to France; but as his measures failed in satisfying the government of his native country, he was recalled in 1796 by President Washington, with an implied censure. Yet this circumstance did not degrade him in the general estimation. In 1799 he was nominated governor of Virginia, an office which he held for three years. He was also appointed minister extraordinary to France, and minister to London in 1803, and envoy to Spain in the following year. In 1806 he was again sent to England to negotiate with the Fox ministry. The important post of secretary of state was bestowed upon him in 1811; and in 1817 he succeeded James Madison as President of the United States. In 1821 he was re-elected by an almost unanimous vote. The government of Monroe was characterized by a vigorous and enlightened patriotism. His attention to the improvement of the army and navy was great, and descended to minute particulars. He made vigorous exertions for the abolition of the slave trade, and encouraged the establishment of the principles of free commerce with all nations. His resolution to defend the independent South American governments against all European interference was bold and at the same time sagacious, and it served its purpose. At the end of his second term Monroe retired from the presidency into private life. He died at New York on the 4th July 1831.

MONROVIA, a seaport-town of West Africa, capital of the Liberian republic, is situated on the Guinea coast, N. Lat. 6. 19., and W. Long. 10. 49. It contains the government-house, the president's residence, and several churches and schools, besides a printing establishment and a head jail. The town was founded in 1821, and now contains about 2000 inhabitants.

MONS (Flem. *Berghen*), a town of Belgium, capital of the province of Hainault, is situated on both sides of the Trouille, which is here crossed by three bridges, 38 miles S.W. of Brussels by railway. It stands partly on a plain and partly on the slope of a hill, is defended by a castle, and is surrounded by fortifications, which are entered by five gates. On the E. of the town are two lakes, by means of which and the river the whole neighbourhood may be laid under water. The streets are in general wide, regular, and well paved, though some are steep and winding; and the houses are handsome and well built. There are eight squares, the most important of which is the Place d'Armes, which contains the government-house and the provincial council-hall. Mons possesses five churches, the principal of which is that of St Wardru, a building in the Gothic style, with one of the finest collections of works of art in Belgium. The chief of the other buildings are the town-hall, a Gothic edifice with a handsome steeple; the castle, court-house, college, theatre, and arsenal. The town has also an academy of music, school of arts, and many other educational institutions; an orphan hospital, a deaf-and-dumb institution, two lunatic asylums, &c. The manufactures of Mons are important and various, consisting of linen, woollen, and cotton stuffs; hardware, fire-arms, musical instruments, soap, oil, candles, earthenware, &c. The chief wealth of the place, however, is derived from the coal-pits in the neighbourhood, in which a large number of men are employed. There are also extensive bleachfields near the town. The trade is considerable in coal, marble, building stone, timber, horses, cattle, corn, and manufactured goods. Mons stands on the railway between Brussels and Valenciennes, and is also connected with Condé on the Scheldt, and by a canal which

Monrovia
||
Mons.

Monselice
||
Monster.

forms part of a communication by water between this town and Paris. It is believed to occupy the site of a Roman camp founded by Cæsar, which was defended with great courage and success by Q. Cicero, the brother of the orator, against several Gallic tribes. In the seventh century it became the residence of Alberic, Count of Hainault, and subsequently increased in size and prosperity, till it was made by Charlemagne, in 804, the capital of Hainault. After undergoing several sieges and changes, it fell into the hands of the Duke of Burgundy. The greatest prosperity to which this town attained was during the reign of Charles V., but this was soon after checked by the exactions of the Duke of Alva; and after an unsuccessful attempt at revolt, the town remained quiet, and gradually declined in importance. In 1678 the Prince of Orange was defeated near Mons by Marshal Luxemburg, who afterwards besieged the town; but his operations were cut short by the peace of Nimeguen. In 1691 it was besieged and taken by the French, who retained the town till the peace of Ryswick. In 1709 the battle of Malplaquet was fought in the neighbourhood of Mons, in which Marlborough and Prince Eugene defeated the French; and the town soon afterwards capitulated to the conquerors. In 1792 the French, under Dumouriez, defeated the Austrians at Jemappes, and afterwards obtained possession of Mons, which was in 1794 declared to belong to France, and made the capital of the department of Jemappes. It was restored to Belgium in 1814. Pop. 23,165.

MONSELICE, a town of Austrian Italy, in the government of Venice, and province of Padua, is situated on a lofty rock, 12 miles S.S.W. of Padua. The principal buildings are an ancient castle, which commands the town, and four churches. Manufactures of woollen stuffs, silk, and hats are carried on here. It has a considerable trade, which is much assisted by the position of the town on a canal connecting Este and Bacchiglione. Pop. 5400.

MONSOON, a regular or periodical wind, in the Indian seas, blowing constantly in the same direction during six months of the year, and contrariwise during the remaining six. (See METEOROLOGY, sect. 67; and PHYSICAL GEOGRAPHY.)

MONSTER, a birth or production of a living being degenerating from the proper and usual disposition of parts in the species to which it belongs; as, when there are too many members, or too few, or some of them are extravagantly out of proportion, either on the side of excess or defect. The word comes from the Latin *monstrum*, a derivative of *monstrando*, showing; and hence also the box in which relics were anciently kept to be shown was called *monstrum*. Dugdale mentions an inventory of the church of York with this article, "*Item unum monstrum cum ossibus sancti Petri in beryl, et crucifixo in summitate.*" Aristotle defines a monster to be a defect of nature, when, acting towards an end, she cannot attain to it, from some of the principles being corrupted.

Monsters do not propagate their kind, for which reason some rank *mules* amongst the number of monsters, as also *hermaphrodites*. Females which bring forth twins are found most liable to produce monsters. The reason probably is, that although the twins are covered with one common chorion, yet they have each their separate amnios, which by their contiguity may chance to grow together, and so occasion a confusion or blending of the parts.

With respect to structure, monsters are of various kinds. Some have an excess or defect in certain parts, such as those which are called *acephalous*, or want the head; those which have two heads, two arms, two legs, and one body, or which have two bodies and one head, or which have three legs; and those which want the arms or the legs. Others err through an extraordinary and deformed conformation, through an unnatural union of certain parts

Monster.

or viscera, through a great derangement in one or more of their members, and through the extraordinary place which these often occupy in consequence of this derangement or transposition. The monster described by Dr Eller of the Academy of Berlin was of this kind. It was a fœtus of nine months, twenty-eight inches long, with an enormous head and frightful countenance: and in the middle of a broad and vast forehead it had a reddish eye, without either eyebrows or eyelids, and sunk deep into a square hole. Immediately below this eye was an excrescence which strongly resembled a penis, with a glans, a prepuce, and an urethra; the part covered with hair was likewise below the nape of the neck. In other monsters we meet with the unnatural union of some parts which, from their destination and functions, ought always to be separate; and the separation of other parts which, for the same reasons, ought constantly to be united. The reader may see the different ways in which the formation of monsters takes place in four memoirs by M. Leméry, inserted in *L'Histoire de l'Académie des Sciences*, 1738 and 1739.

In the volume published by the Academy of Sciences in the year 1724, mention is made by M. Geoffroy of a monster born in Barrois, 1722. This monstrous production consisted of two children without the inferior extremities, and joined together by a common navel. Each of them had a nurse, sucked, and eat pap; and the one sucked whilst the other slept. The reader may likewise consult the second part of Winslow's *Memoirs on Monsters*, inserted in the volume published by the Academy of Sciences in 1734, where he will find the history of the two very extraordinary twin monsters who exhibited during their lives a great difference in their moral and physical qualities. We are obliged to refer simply to these memoirs, as they are too long for abridgment.

It is observed by Haller, that in some monsters the natural structure has been changed by some shock or passion, whilst in others the structure, independently of any accident, appears to have been originally monstrous; such as when all the members are reversed from left to right, when the person has six fingers, and in many other instances. M. Renou, surgeon at Pommeraye, in Anjou, published an account of some families with six fingers, who were to be found in several parishes of the Lower Anjou, and which had existed there from time immemorial. This deformity was perpetuated in these families even when they intermarried with persons who were free from it. Whether the propagation of these supernumerary organs, which are not only useless, but inconvenient, and even disagreeable, be owing to the father or mother, the children of both sexes are subject to it indiscriminately. A father and mother with six fingers frequently have a part, and sometimes the whole of their children, free from this deformity; but it again makes its appearance, and in a very great degree, in the third generation. From this it appears that such a fault in the conformation is hereditary. (The reader may consult the *Journal de Physique* for November 1774, p. 372.) This variety of *sexdigitary* hands and feet is not comprehended in the *Recherches sur quelques Conformations Monstrueuses des Doigts dans l'Homme*, which is inserted in the Memoirs of the Academy of Sciences for 1771. In the *Journal de Physique* for August 1776, we find a description of a double uterus and vagina observed in a woman who died in childbed, by Dr Purcell of Dublin; and in that for June 1788 we have an account, by Baron Dietrich, of a man with seven fingers on each hand. (See also the curious work of Dr Barkow, entitled *Monstra Animalium per Anatomen indagata*, ii., 4to, Leips., 1828-36.)

Three opinions have been advanced by physiologists as to the causes of monstrosity by excess:—1. Duverney, Winslow, and Haller ascribed excess of organs to the coalition of two perfect germens. 2. Wolf and Meckel

Monster. considered it as owing to an original excess of productive power. 3. The celebrated Tiedemann ascribed it to abnormal vascular action, modified by pressure. The first opinion has been adopted by Treviranus, Otto, Burdach, Rudolphi, Mayer, and Müller: the second has been defended by Bâer and Himly; while the third has been maintained by Serres and Geoffroi St Hilaire. (For further information on the subject, see *Lectures on Medical Jurisprudence*, by Dr Traill.)

Monsters are more common and more extraordinary in the vegetable than in the animal kingdom, because the different juices are more easily deranged and confounded together. Leaves are often seen, from the internal parts of which other leaves spring forth; and it is not uncommon to see flowers of the ranunculus from the middle of which issues a stalk bearing another flower. Bonnet informs us, that in certain warm and rainy years he has frequently met with monsters of this kind in rose trees. This observer saw a rose from the centre of which issued a square stalk of a whitish colour, tender and without prickles, which at its top bore two flower-buds opposite to each other, and totally destitute of a calyx; and a little above the buds issued a petal of a very irregular shape. Upon the prickly stalk which supported the rose, a leaf was observed which had the shape of a trefoil, together with a broad flat pedicel. In the Memoirs of the Academy of Sciences for 1707 mention is made of a rose from the centre of the leaves of which issued a rose branch two or three inches long, and furnished with leaves. In the Memoirs for 1775, a singular instance is mentioned of a monstrosity observed by Duhamel in an apple tree ingrafted with clay. At the place of the insertion there appeared a bud which produced a stalk and some leaves; the stalk and the pedicel of the leaves were of a pulpy substance, and had the most perfect resemblance both in taste and smell to the pulp of a green apple. An extraordinary *chamamelum* is mentioned in the *Acta Helvetica*. Bonnet, in his *Recherches sur l'Usage des Feuilles*, mentions likewise some monstrous productions which have been found in fruits with kernels, analogous in their nature to those which occur in the flowers of the ranunculus and of the rose tree. He observed a pear from the eye of which issued a tuft of thirteen or fourteen leaves, very well shaped, and many of them of the natural size. He noticed a second pear which gave rise to a ligneous and knotty stalk, on which grew another pear somewhat larger than the first. The stalk had probably flourished, and the fruit had formed. Reynier has mentioned some individuals monstrous with respect to the flower, in the *Journal de Physique et d'Histoire Naturelle* for November 1785.

These vegetable productions, which are so extraordinary and so contrary to the common course of things, do nevertheless present deviations subject to particular laws, and reducible to certain principles, by distinguishing such as are perpetuated either by seed or by transplanting from those which seem to be only accidental. Monstrosities which are perpetuated exist in the original organization of the seed of the plant, such as marked or curled leaves, &c. The word *monster* is more properly applied to those irregularities in plants which arise from frequent transplantation, and from a particular culture, such as double flowers; but those monstrosities which are not perpetuated, and which arise from accidental and transient causes deranging the primitive organization of the plant when it comes to be unfolded, being the effect of diseases, of heat or cold, of a superfluity or scarcity of juices, of a deprivation of the vessels contributing to nutrition, of the sting of insects, and of contusions and natural grafts, retain also the name of *monsters*. Of this kind are knobs or swellings, stunting, gall-nuts, certain streaks, the inoculation of branches, and other similar defects.

MONSTRELET, ENGUERRAND DE, a French chronicler, was born of a noble family, and flourished in the first half of the fifteenth century. He was provost of the city of Cambrai and bailiff of Wallaincourt; and he died in 1453. His *Chronicle* narrates with simplicity and truth, but with great diffuseness, the capture of Paris and of Normandy by the English, and the wars between the houses of Orleans and Burgundy. The first book begins with 1400, the year at which the chronicle of Froissart stops, and ends with 1422; the second stops at 1444. There is a third book, bringing down the history to 1453, which Buchon, the best editor of Monstrelet, considers to be spurious. The edition of Buchon was published in 15 vols. 8vo, Paris, 1826-7. Johnes, the translator of Froissart, translated Monstrelet into English, in 5 vols. 4to, 1810.

MONT DE PIÉTÉ (Ital. *Monte di Pietà*), a public benevolent institution established in Italy in the 15th century, by the Papal and other Italian governments, for lending money to the necessitous at a limited rate of interest. With the design of putting a check upon the usurious Jewish money-lenders of that age, Leo X., or according to some, Paul III., sanctioned the first establishment of a Monte di Pietà at Rome, which was a sort of bank, under the direction of a society of wealthy persons, who supplied the necessary funds, and lent upon pledges small sums for a fixed term at a low rate of interest. The interest charged was meant to defray the necessary expenses of the institution; and the funds were administered on the most economical and equitable principles, with the sole design of benefiting the borrower. Similar establishments were afterwards set on foot throughout the most of the Italian towns, and soon extended to the Netherlands and to Spain. These institutions, which are still in existence in Italy, were plundered by the French under Napoleon during the Italian invasion of 1796-7; and the Pope himself was obliged during the same period to seize upon the pledges of the Monte di Pietà, to enable him to pay the war contributions exacted by the French.

The *Monti Frumentarii* are granaries established in different parts of Italy to supply the needy with grain on the same principle as that on which money is lent by the Monti di Pietà.

MONTAGNANA, a town of Austrian Italy, in the government of Venice, and province of Padua, is situated 22 miles S.W. of Padua. It is defended by walls and high towers, built of brick, and affording an excellent specimen of the fortification of the middle ages. The town has several old churches, one of which, of the fourteenth century, in the Italian-Gothic style, stands in the Piazza or principal square. There are also at Montagnana a castle, a theatre, a female school, and an hospital. The manufactures consist of woollen and linen stuffs, leather, and hats; and there is some trade in agricultural produce. Pop. 9800.

MONTAGU, BASIL, Queen's counsel, was the natural son of the fourth Earl of Sandwich and of that Miss Ray who was shot in the piazza of Covent Garden, in 1779, by her jealous lover, a clergyman of the name of Hackman. He was born in April 1770. His early education was received at the Charter-House School in London; and he studied and took the degree of M.A. at the university of Cambridge. He afterwards entered Gray's Inn, and was called to the bar in 1798. His professional eminence, however, was not the result of his power of pleading, but of the numerous works which he continued to write. The most important of these was *A Digest of the Bankrupt Laws*, &c., which was published in 4 vols. in 1805, and which secured for him the office of commissioner of bankrupts. Montagu was also distinguished for his exertions to mitigate the severity of the penal code. He wrote several pamphlets on capital punishments; and in conjunction with

Monstrelet
||
Montagu.

Montagu. Wilberforce, Romilly, and others, he succeeded in abolishing hanging for forgery. To the reader of general literature, however, he is best known as the friend of Coleridge, and the editor of an elaborate edition of Bacon's works in 16 vols. He died at Boulogne in November 1851.

MONTAGU, *Lady Mary Wortley*, was the eldest daughter of Evelyn Pierrepont, Duke of Kingston, and Lady Mary Fielding, daughter of William, Earl of Denbigh, and was born at Thoresby, Nottinghamshire, in the year 1690. She was connected through the Pierreponts with Beaumont the dramatist. Villiers, Duke of Buckingham, was her grand-uncle, and Henry Fielding was her second cousin. Having lost her mother at the age of four, her education was left to a sensible grandmother, a superstitious nurse, and a weak governess. Under the tuition of her brother's preceptors, she acquired some knowledge of Latin, a smattering of Greek, and the rudiments of the French language. At the age of eight she had made considerable proficiency, and began to read all the books she could lay her hands on. Her first known poetical effusion was an *Épistle from Julia to Ovid*, written at the age of twelve, and which, besides the complimentary gallantry, exhibits a nice apprehension of the style of versification then in vogue. At fifteen she formed a project of establishing an English nunnery, and of electing herself lady-abbess, but had not the means to carry out her scheme. At twenty she translated Epictetus, most probably from the Latin version, under the eye of her friend Bishop Burnet.

The next step of importance in the life of Lady Mary was her marriage with Edward Wortley Montagu, son of the Hon. Sydney Montagu, and grandson of the first Earl of Sandwich. He was a country gentleman, not remarkably brilliant, but possessed of considerable scholarship. The marriage seems to have been ill-assorted, and certainly proved unfortunate. A radical incongruity of character existed between them which time could not correct.

In 1714 Mr Wortley obtained a place in the Treasury, and in consequence took his lady to court, where her wit, spirit, and beauty attracted general admiration, and made a considerable impression on the Prince of Wales, afterwards George II. In 1716 Mr Wortley, who had made no great figure at home, was appointed ambassador to Constantinople, where his success was not more remarkable. But he took his wife with him to the capital of the Turkish empire, and thus afforded her an opportunity, in her *Letters from the Levant*, of charming the world with the most luxurious pictures ever yet given of a voluptuous people, and of bringing away with her, in the shape of inoculation for small-pox, a talisman for the preservation of beauty. From these, and indeed from all her future letters, it is clear that her good sense was sound and uncompromising, with an ever-increasing tendency towards universal justice. Besides Constantinople, Lady Mary and her husband, whilst abroad, visited several parts of Germany; and on their return sailed through the Archipelago, touched on the coast of Africa, and, crossing the Mediterranean to Genoa, reached home through Lyons and Paris in October 1718. From all these places we have letters of the liveliest kind, and, considering the time at which she wrote, of the most original description. A traveller so shrewd and observant was till then unknown, and her sex gave to the novelty an additional attraction. The manners of Italy she found peculiarly congenial to her disposition; and accordingly, when in 1739 she resolved to pass the remainder of her life on the Continent, she betook herself to that country, and remained there until within less than a year of her death.

On her return from the East, Pope prevailed on her to come and live near him at Twickenham. Both were then in the zenith of their reputation, and mutual admiration seemed to give assurance of the stability of their friendship.

But a short time sufficed to prove that this anticipation was ill founded. Various causes have been assigned for the sudden rupture which ensued. According to Lady Mary's own statement, the truth of which is borne out by other evidence, Pope at some ill-chosen time made such passionate love to her, as, in spite of her utmost endeavours to be angry and look grave, provoked an immediate burst of laughter, from which moment the mortified poet became her implacable enemy.

On her return from Constantinople, she introduced inoculation for the small-pox into England, through the medium of the medical attendant of the embassy. She had lost her only brother by the disease, which had also destroyed her own beautiful eye-lashes; and she was resolved to give to her family and the world the benefit of a practice which promised to save the lives and to preserve the beauty of millions. With courageous love, she began with her own offspring, and lived to see her innovation triumphant, though not until it had encountered such an opposition that she almost repented of her philanthropy. In the month of July 1739 she left England without her husband, with a resolution to pass the remainder of her life on the Continent. She proceeded at once to Venice, and took possession of a deserted palace on the banks of Lake Iseo, in the Venetian territory, where she planned a garden, applied herself to the business of a country life, and solaced herself with books, which in some measure supplied the want of society. On the death of Mr Wortley, which took place in 1761, she yielded to the solicitations of her daughter, Lady Bute, and after an absence of twenty-two years, returned to England. But her health had suffered much from a cancer with which she was afflicted; and before ten months had elapsed, she expired, on the 21st of August 1762, in the seventy-third year of her age. Lady Mary Wortley Montagu was undoubtedly the most remarkable woman of her time. She was the presiding female wit in the days of Pope, the benefactress of her species by the introduction of inoculation, and the keen satirist of the fashionable circles. Her poems are indeed little else than wit in rhyme,—mere *vers de société*; but her prose is truly admirable. It is idiomatic, easy, fresh, racy, and piquant; sparkling with wit, and often equally remarkable for strong sense and sarcastic bitterness. The conventional shows of things could not deceive her; she saw beneath the painted masks which are worn in society, and fearlessly published her discoveries. It is only to be regretted that she occasionally overlooked what was worthy in human nature, and wasted her fine powers on objects that only served to embitter her life.

The best edition of her *Letters and Works* is that published by her great-grandson Lord Wharnccliffe, London, 1837, in 3 vols. 8vo, containing a very spirited life of Lady Mary, under the title of *Biographical Anecdotes*, supposed to be from the pen of her grand-daughter Lady Louisa Stuart. A new edition of her *Letters* appeared in New York in 1856, in vol. ii. of *The Library of Standard Letters*.

MONTAGU, *Edward Wortley*, only son of Edward Wortley Montagu, Esq., and Lady Mary, the subject of the preceding article, was born at Wharnccliffe in Yorkshire in October 1713. In 1716 he accompanied his parents to Constantinople, and, on their return to England in 1718, was placed at Westminster School. Here he gave the first indication of his wayward disposition by running away, and eluding all search, until about a year afterwards, when he was accidentally discovered at Blackwall, with a basket of fish on his head, having bound himself, by regular indenture, to a poor fisherman. Emancipated from this degrading condition, he was again placed at Westminster School; but ere long he absconded a second time, and bound himself to the master of a vessel engaged in the Oporto trade,

Montaigne. who, supposing him a friendless boy, treated him with great kindness and humanity. He had scarcely landed at Oporto, however, when he ran away, and contrived to get employment for two or three years in tending vines. Here he was at length discovered, brought home, and, on promise of amendment, pardoned; but unhappily with no better effect than before. He ran away a third time, after which his father procured him a tutor, who so far reclaimed him to habits of regularity, that he obtained an appointment in one of the public offices. In 1747 he was elected one of the knights of the shire for the county of Huntingdon; but he does not appear to have in any way distinguished himself as a member of Parliament, nor did he long retain his seat, his expenses having so far exceeded his income, that towards the close of the year 1751 he found it prudent once more to leave England. He proceeded to Paris, where in a short time he was imprisoned in the Châtelet for some fraudulent gambling transaction in which he had been concerned, but soon effected his escape. In the Parliament which assembled in 1754 he was returned for Bossiney. Besides some dull communications to the Royal Society, he published a book on the *Rise and Fall of the Ancient Republics*, the merit of which was afterwards claimed by his tutor, Mr Foster. His father died in the year 1761, at an advanced age, and by his will bequeathed to his son a considerable annuity. His mother died in the year 1762, and left him only one guinea. He had offended her irreconcilably by his misconduct. But as his father's bequest had rendered him independent, he took a final leave of his native country, passed the remainder of his life in foreign parts, and died at Padua in 1776. Before his death he became first a Catholic and then a Mohammedan, in which latter character he ended his days. He travelled in the East; and among other pieces is said to have published an *Explication of the Causes of Earthquakes*.

MONTAIGNE, MICHEL SEIGNEUR DE, was descended from an ancient English family named Eyquem, and was born at the castle of Montaigne, in Périgord, on the 28th of February 1533. His father, a brave and loyal squire, who had served in Spain and Italy, where he had cultivated his mind and improved his taste, bestowed much attention on his education, and in particular initiated him into the knowledge of languages by a process much less tardy and laborious than that ordinarily pursued in schools. He provided his son with a German master, who, being entirely ignorant of French, but well versed in Latin, spoke to him only in the latter tongue, which he consequently acquired as a vernacular language, and at the age of six was able to converse in it with tolerable freedom and fluency. Greek was also taught him as a sort of diversion. By means equally attractive, he was led to acquire some knowledge of science; and, without forcing his inclination or imposing the necessity of severe application, his habits were formed, and his powers agreeably exercised. All this care and attention he repaid by the most tender affection for the memory of his father; indeed filial piety is said to have formed a conspicuous trait in his character, though it must be confessed that he sometimes displayed it in a manner sufficiently singular. At an early age he was sent to the college of Guienne at Bordeaux, then the most flourishing in France, where he had as masters Nicolas Grouchy, William Guérente, George Buchanan, and Muret, under whom he appears to have made considerable proficiency. Having completed his studies at the age of thirteen, Montaigne resolved to study law; and in 1554 he became a counsellor or advocate at Bordeaux, and continued to practise as such until the death of his elder brother, when he abandoned a profession to which he never had any real liking, and which he appeared afterwards to consider as derogatory. In 1566 he married Françoise de la Chassaigne,

to please his friends, he says, rather than himself, for he Montaigne. was not much disposed for a married life. He, however, proved a faithful husband, and enjoyed the matrimonial state much better than he had "promised or hoped." But he reconciled himself, as he says in his own familiar, gossiping, satirical way, by reflecting that "it is too late to kick when the fetters are on." He had one daughter as the fruit of this marriage.

At his father's request, Montaigne translated in 1569 the *Theologia Naturalis* of the Spanish divine Raymond Sebonde; and in 1571-2 edited the posthumous works of his lamented friend Etienne de la Boétie. He kept aloof from public affairs during the civil and religious dissensions then desolating France, and thus rendered himself obnoxious both to the Protestants, with whom he really sympathized, and to the Roman Catholics, to whom he was attached by the ties of education and loyalty. His feelings were as humane as his sentiments were liberal; and the horrors of St Bartholomew plunged him into a deep melancholy. For the improvement of his health, and with a view to the study of men and manners, he travelled through various parts of France, Germany, Switzerland, and Italy, making observations on everything curious or interesting in society, and receiving several marks of distinction in the course of his peregrinations. The private journal which he kept of this tour was discovered two centuries afterwards, and published under the title of *Journal de Voyage de Michel de Montaigne en Italie, par la Suisse et l'Allemagne, en 1580-81*, Paris, 1774. It was about this period that he began to write his celebrated *Essais*, which were published in March 1580. In 1581 he was admitted a citizen of Rome, in which city he then sojourned; and the same year he was elected mayor of Bordeaux, an office in which he seems to have given much satisfaction to his fellow-citizens. In 1582 he was sent on a special mission to court about some affairs of importance; and on the expiration of his mayoralty he was again elected to the same office. In 1588 he appeared to some advantage at the assembly of the states at Blois, and, though not a deputy, took a share in the proceedings, but on what pretence or in what capacity does not clearly appear. During one of his visits to court he received the cordon of the order of Saint Michel, a distinction which he appears to have greatly coveted, though we afterwards find him complaining of the discredit into which it had fallen. Having retired to his family residence, he devoted himself to study; but his tranquillity was disturbed by the civil wars which desolated Guienne; and being driven from his house, he wandered about during six months seeking shelter for his family, and often with difficulty obtaining an asylum amongst those who had shared his hospitality. It appears, from a statement of De Thou, that Montaigne had sought to bring about a reconciliation between the Duke of Guise and the King of Navarre, afterwards Henri IV.; and on his return from Paris, where he had completed a new impression of his *Essais* in 1588, he was with the historian at Blois when the Duke of Guise was there assassinated. In his old age he was very much afflicted with stone and nephritic colic; but he never could be prevailed on to take medical advice. He died on the 13th of September 1589, and was buried in the church of the Feuillants at Bordeaux, where a monument was erected to his memory. Notwithstanding his constitutional tendency to scepticism, and certain unguarded expressions which seem almost to intimate an entire absence of the sentiment of religion, he is said to have died a Christian. He at all events had mass celebrated in his chamber in his last moments, and expired during the elevation of the host.

To form anything like a correct idea of Montaigne, it is absolutely necessary to make a study of his *Essais*. Nothing but a weak and dwarfish picture of the man could be

Montaigne. formed from selections or quotations from his familiar pages, however judiciously made. His book, he informs us, is about himself, and himself alone. Whatever else of anecdote, speculation, narrative, or remark, is introduced into it, has only a place there from its relation to the living centre around which it has been collected. In what to him seemed a wide sea of conflicting opinion, shoreless and without a horizon, the only fixed and really tangible object he considered to be himself. To disclose himself, accordingly, in all phases of his nature, whether of strength or weakness, nobility or meanness, beauty or deformity, wisdom or folly, he made the business of his calm, meditative life. He records his virtues and his vices, his merits and his defects, with a familiar candour and easy simplicity which at once disarms criticism and secures sympathy. One feels, as he listens to this strange blending of simple gossip and deep wisdom, told in an easy, rambling, picturesque style, as if he occupied a seat in that small round study of Montaigne's, with its "three noble and free prospects," from "the third storey of a tower" of his high, windy Montaigne Castle, and enjoyed the close and familiar friendship of this robust, indolent, thoughtful old Gascon. As to his personal appearance, he was of low stature, he informs us: "I am, as to the rest, strong and well-knit; my face is not puffed, but full; my complexion, betwixt jovial and melancholic, moderately sanguine and hot." He deplores his incorrigible awkwardness and want of personal dexterity. "My hands are so clumsy that I cannot so much as write so as to read it myself." He consoles himself, however, for these physical defects by the reflection, that "my bodily qualities are very well suited to those of my soul; there is nothing sprightly, only a full and firm vigour. I am patient enough of labour and pains; but it is only when I go voluntarily to the work, and only so long as my own desire prompts me." (*Essais*, t. ii., c. 17.) He dwells now upon his want of memory and his perfect truthfulness,—upon his occasional absence of mind,—upon his dislike of ceremony and love of politeness,—and upon his disbelief in omens and ghosts. Again, he has a profound sense of the sad instability of all human affairs, becomes gravely thoughtful, and shows symptoms of a real though passing melancholy as he meditates on death. He wore for his device a balance, with the characteristic motto, "*Que sçay je?*" was vain of his cordon of honour, and was fond of showing his coat of arms. He was strongly averse to all cruelty and malignity of feeling, and never fails to denounce injustice, inhumanity, and uncharitableness.

His reputation as a writer is founded solely on his *Essais*, which were at one time extremely popular, and which are still read by a numerous class. As a writer, he imparted to the French language an energy which it did not before possess, and which but few of his successors have equalled. As a philosopher, his object was to describe man as he is, without reserve and without exaggeration; he studied himself, and recorded his observations with surprising acuteness and fidelity. He united in a high degree the powers of observation and reflection, without which the study of man can never be successfully prosecuted; and although there is no doubt much truth in the acute but severe strictures on his character by the Port-Royalists, who freely expose his vanity, his self-love, and the indulgent manner in which he speaks of his vices; yet, as Mr Stewart observes, "this consideration, so far from diminishing the value of his *Essais*, is one of the most instructive lessons they afford to those who, after the example of the author, may undertake the salutary but humiliating task of self-examination." In the first *Preliminary Dissertation* (part i., section ii.), to which the reader is referred, will be found an exposition and criticism of Montaigne's philosophy. Montaigne's Life was first written by the President Bouhier, and prefixed to a supplementary volume of his works in 1740. In 1774 the

Academy of Bordeaux awarded a prize to Talbert for an *éloge* on Montaigne; and the French Academy bestowed a similar honour on Villemain in 1812. This masterly *éloge* is attached to the 8-vol. edition of Montaigne's *Essais*, Paris, 1825. The best English translation of the *Essais* is that of Cotton, first published in 1700, but revised and corrected in 1759.

Since the above was written a new *Life of Montaigne* has been published by Bayle St John, Lond. 1857. (For valuable papers on Montaigne, see Sterling's *Essays and Tales*, Emerson's *Representative Men*, and *Oxford Essays* for 1857.)

MONTALEGRE, a town of Brazil, in the province of Para, is situated on an island in the Amazon, near the mouth of the Gurapatuba, 150 miles E.N.E. of Para. It has a church, a saw-mill, and a considerable trade in mandioc, cotton, cocoa, coffee, &c. Pop. 4000.

MONTALEMBERT, MARC-RÉNÉ, MARQUIS DE, a distinguished French engineer, was descended from a noble and ancient family, and was born in July 1714, at Angoulême. After receiving an education suitable to his birth, he entered the army at the age of eighteen, and was present at the sieges of Kehl and Philipsburg. He was next engaged in the war with Bohemia. On the conclusion of peace he turned his attention to the cultivation of those sciences upon which the military art is founded. He became a member of the Academy of Sciences in 1747, and contributed to its Memoirs several papers on fortification. He also established forges at Angoumois and Périgord, for the purpose of supplying the French navy with cannons and projectiles. During the Seven Years' War the important post of French agent in the Russian and Swedish armies was entrusted to him. In 1776 he began to publish at Paris his *La Fortification Perpendiculaire, ou l'Art Défensif supérieur à l'Offensif*, a large work, which was completed in eleven volumes in 1796. Meanwhile he had been charged in 1779 with the task of fortifying the Isle of Aix against the attacks of the English. The wooden fort, which he constructed on a new plan, proved efficient in spite of the prognostications of his fellow-engineers. By these efforts for the promotion of military art Montalembert brought himself into debt, and was compelled to sell his foundries to the government. But the price of them could not be obtained even after frequent applications. It is no wonder, therefore, that, aristocrat though he was, he became a supporter of the principles and practices of the French revolution. A pension, awarded to him for the loss of an eye during his services to the government, was resigned for the behoof of the state; and, like a true democrat, he divorced his wife to make room for the daughter of an apothecary. In return for such conduct he was allowed to recover his sequestered estate, and to sell it for the supply of his wants. The assignats, however, which he received as the price, fell immediately in value, and left him as poor as ever. Towards the close of his life Montalembert recommended himself to the notice of the Committee of Public Safety; and was frequently consulted by Carnot on the subject of military operations. He died of dropsy in March 1800. Besides his chief work, already mentioned, Montalembert wrote *Correspondance pendant la Guerre de 1757*, 3 vols. 8vo, 1777; *L'Ami de l'Art Défensif*, 4to, 1796; and *Relation du Siège de Saint-Jean-d'Acre*, 8vo, 1798.

MONTALVAN, JUAN PEREZ DE, an eminent Spanish dramatist, was the son of the King's bookseller, and was born at Madrid in 1602. His youthful genius was stimulated by the example, and guided by the advice and assistance, of the great dramatic writer Lope de Vega. So strong, indeed, was the mutual esteem between the two poets, that the elder treated the younger as a son, and the younger adopted the elder as his model in almost everything. Like his admired master, Montalvan entered the

Montanaro
||
Montanus.

priesthood, and accepted an office in the Inquisition. He was also a most voluminous writer. By his thirtieth year he had produced thirty-six dramas; and in 1636 the number had increased to about sixty. In their success, as well as in their flimsy construction and careless execution, he likewise resembled Lope de Vega. One of the last works of Montalvan was an extravagant panegyric on his great friend, published in 1636. By this time his intense and incessant labours had begun to derange his brain. Not long afterwards he fell into a state of imbecility, which continued till his death in June 1638. Montalvan's collected dramatic works appeared in 1638-39, and were reprinted in 1652.

MONTANARO, a town of Piedmont, in the province of Turin, is situated near the Orco, 14 miles N.N.E. of Turin. It is well built, and has two squares, a church, a castle, a court-house, and several schools. Some trade is carried on here in cattle and tobacco. Pop. 4400.

MONTANCHES, a town of Spain, in the province of Caceres, is situated in a hilly region, 20 miles S.E. of the town of Caceres. The streets are steep and well paved; the principal buildings are a town-house, prison, church, nursery, and several schools. The town has many flour and oil mills; but it is chiefly noted for the excellence of its hams. Pop. 5587.

MONTANUS, the founder of the sect of the Montanists, appeared as a teacher of new doctrine at the village of Ardaban, on the borders of Phrygia, about the middle of the second century. At that time the church was suffering under bloody persecutions from without and distracting heresies from within. In his burning desire to cheer and enlighten her, Montanus began to imagine himself to be the passive instrument in the hands of God for dispensing new revelations. He foretold the near approach of those judgments that would sweep all persecutors from the earth, of the second advent of Christ, and of the commencement of the blessed millennium. With such a prospect at hand he admonished all Christians to live soberly and righteously, and more especially to risk all for the martyr's crown. At such startling announcements many scoffed; but others, including two females of fortune, Maximilla and Priscilla, became converts, and fell immediately into ecstasies of exhortation and prophesying. Stimulated by this success, the delirious imagination of Montanus began to create more portentous delusions. He fancied himself to be an inspired prophet sent to the entire church to complete the code of moral duties, to extinguish all heresies by new light from on high, and to prepare the church for the coming of her Lord. He even pointed out a paltry Phrygian village, called Pepuza, as the future site of the New Jerusalem.

Such presumptuous ravings, in order to merit the name even of heresy, required a systematic arrangement which the crazed brain of Montanus was too weak to execute. This arrangement was afterwards effected by Tertullian, the greatest of the Montanists, and may be represented in the following outline:—Christianity, like all the other works of God, undergoes a gradual development, and is constantly approaching perfection. This developing process may be distinctly seen running through the successive ages of the patriarchs, the prophets, and the teachers of the New Testament. But in the last of these periods it had not attained perfection; for Christ explicitly foretold the coming of a Comforter who should elucidate all the mysteries of the truth; and even after the death of the apostles there remained pagan practices to be condemned, heresies to be refuted, and obscure passages in the Scripture to be explained. It therefore stands to reason that the Spirit of God, the same in all ages, should descend with resistless influence in these latter times, as in the days of the Hebrew prophets and at Pentecost, and should fill certain chosen vessels with that supernatural illumination which is to light

the church on to perfection. Accordingly Montanus, like the Apostles, became the passive recipient of the Holy Ghost. Nor was the supernatural gift restricted to the priests, who claimed to be successors of the Apostles. Christians of every grade fell into divine rhapsodies, and even women, as Joel had foretold, began to prophesy.

The precepts with which these enthusiastic teachers eked out the moral code were, as might have been anticipated, full of severe asceticism and a stoical contempt of pain. The old fasts were prolonged, and new fasts were added. Those who were guilty of the more deadly crimes were excluded from the church for ever. Martyrdom was held up as the great object of ambition, and to attempt to shun this kind of death, or to wish for any other, was denounced as a sin. Those believers who wished to become superior channels for the stream of revelation passing from heaven to earth, were required to remain in celibacy. Marriage was defined to be a bond, not merely bodily and temporal, but also spiritual and eternal; and therefore they who married a second time were treated as adulterers. A denouncement also fell upon all usages and all arts and sciences that arose during the reign of heathenism.

The followers of Montanus, in the midst of much controversy and persecution, continued to increase under the several names of *Montanists*, *Cataphrygians*, and *Pepuzians*; they were found in Asia, Africa, and a part of Europe. They still existed in the time of Augustine and Jerome. (See Neander's *History of the Church*.)

MONTARGIS, a town of France, capital of an arrondissement of the same name, in the department of Loiret, is situated on the Loing, 40 miles E.N.E. of Orleans. The town, which is partly walled, is well but irregularly built, and formerly contained a castle, which was entirely destroyed in 1809. Montargis has a church, two hospitals, and a theatre. Manufactures of cloth, leather, and paper are carried on here; and the town has a considerable trade in cattle, corn, honey, wax, leather, &c. Pop. 7757.

MONTAUBAN, a town of France, capital of the department of Tarn-et-Garonne, is situated on an elevated plain on the right bank of the Tarn, which is here crossed by a brick bridge of seven arches, 342 miles S. by W. of Paris. It is small and irregular, and the houses ill built; but on the other side of the river stands a suburb called Ville Bourdon, which is regularly and well built. The town itself has three squares, one of which, called the Place Royale, is large and surrounded by handsome houses. There is a fine promenade called Les Terrasses, which commands an extensive view of the surrounding country as far as the Pyrenees and the sea. Montauban was formerly strongly fortified; but the only remains of its defences at present are its gates. The principal buildings are,—the cathedral, a cruciform building in the Italian style, with two turrets; the church of St James; the prefecture; the town-hall, a square building with four turrets; and the bishop's palace. Montauban has also a college and several other educational institutions. The manufactures are extensive, consisting of silk, woollen, and cotton stuffs, leather, starch, soap, earthenware, brandy, &c.; and some trade is carried on in these articles and the produce of the neighbourhood. Montauban has a court of first resort, a tribunal of commerce, a chamber of manufactures, a public library, and a society of agriculture, science, and literature. Five fairs are held here annually. Montauban was founded in 1144 by Count Alphonse of Toulouse. At the Reformation the people embraced the Protestant cause; and the town was ineffectually besieged by the adverse party in 1580. It afterwards, in 1621, resisted for three months the assaults of Louis XIII., and did not yield till after the fall of Rochelle in 1629. The fortifications were soon after destroyed. The Ville Bourdon was founded by Protestants expelled from Montauban in 1562. Pop. (1851) 23,314.

MONTBELLIARD, or **MONTBÉLIARD** (German *Mumpelgard*), a town of France, capital of an *arrondissement* of the same name, in the department of Doubs, is situated at the confluence of the Allan and the Luzino, 48 miles N.E. of Besançon. The town is well built, and adorned by several fountains. The principal buildings are,—the castle, now used as a prison, situated on an eminence; the town-hall; and the churches of St George and St Martin. The manufactures consist of silk, cotton, and woollen fabrics; leather, clocks, watches; scythes, and other implements of husbandry. There is also an active trade carried on in timber, corn, cheese, &c., with Switzerland and the south. Montbelliard was in former times a place of some strength, and the capital of a county that originally formed part of the kingdom of Burgundy, but was transferred to the Wurtemberg family in 1395. Although twice taken by the French in the seventeenth century, it was not finally ceded to them till 1796. Pop. (1851) 5605.

MONT BLANC, the highest mountain in Europe, belongs to the Pennine Alps, and is situated on the confines of Savoy and Piedmont. This mountain, along with the adjacent branches, forms an oval mass, extending from N.E. to S.W., between Mont Catogne, above Martigny, and the Col du Bonhomme, a distance of 30 miles; and having a breadth of 13 miles between Chamouni and Courmayeur. The appearance of Mont Blanc, when viewed from Chamouni, is that of a round smooth summit, covered with snow, and towering above the other peaks of the same group. The colour of the summit is generally an orange-yellow when lighted by the sun; but at sunset and sunrise the most remarkable and beautiful changes of appearance take place. When the sun's rays have ceased to illuminate the lower mountains, and Mont Blanc alone has the light of the sun still shining on it, its bright hue appears much brighter by reason of the contrast with the surrounding darkness; it assumes a clear roseate tint, and its lustre is sometimes nearly equal to that of the stars. Soon after, however, this brightness passes away as the sun's light is gradually withdrawn, and the mountain assumes a pale-blue appearance. This is owing to the contrast between the mountain, now in the shade, and the thin clouds and vapours which hang above it, and are still lighted by the sun. The geological structure of the central mass of Mont Blanc, as well as of the group of mountains to which it belongs, is granite; but on the sides are found strata of limestone, sloping upwards from the centre; while on the further side of the valleys by which the mountain group is bounded, the limestone strata slope in an opposite direction; and beyond these granite is again found. From the central summit of Mont Blanc many ridges branch out in all directions; between which are ravines, filled with glaciers, and sloping down to the valleys on each side. These valleys are four in number, and form the separation between the group of Mont Blanc and the rest of the Alps. They are separated from each other by ridges, called *cols*, of comparatively small height, which join Mont Blanc at various points to the other mountains. The valley of Chamouni lies to the N.W. of Mont Blanc, and is bounded at its head by the Col de Balme. It is watered by the Arve, which flows in a S.W. direction to the foot of the valley, where it turns N.W., and flows round the Col de Voza and the Col de Forclaz, which separate the valley of Chamouni from that of Montjoie. The latter valley, which bounds Mont Blanc on the W., is traversed by the swift stream of Bon Nant, which flows northward, and joins the Arve below the point where these two valleys finally unite. The head of the valley of Montjoie is formed by the Col du Bonhomme and the Col des Fours, on the S. side of which rise the head waters of the Isère, which flow directly away from Mont Blanc. The S.E. and E. boundaries of the mountain group are formed by the Allée Blanche and

the valley of Ferret. The head of the Allée Blanche is formed by the Col de la Seigne, from which the valley extends in a N.E. direction, being traversed by one of the main streams of the Doire, a tributary of the Po. The other branch of this river flows in an opposite direction, from the Col de Ferret through part of the valley of Ferret; and both streams join a short distance above Courmayeur. The Col de Ferret divides the valley of the same name into two parts, or rather into two distinct valleys, the Piedmontese and the Swiss, the latter of which extends northwards as far as Mont Catogne, the north-eastern extremity of the group of Mont Blanc. The Col de la Forclaz extends to the N. between Mont Catogne and the Col de la Balme. The main ridge of the Alps consists of the Col de Ferret, which extends eastward to the Great St Bernard, and the Col de Seigne, which stretches southward to the Little St Bernard. The principal glaciers which descend into the valley of Chamouni are,—the Glacier du Tour, the Glacier d'Argentière, the Glacier des Bois, the Glacier des Bossons, and the Glacier de Tacconay; in the valley of Montjoie the chief are those of Bionnassay, Niage, and Trelaile; in the Allée Blanche,—the Glacier de l'Estellette, the Glacier de l'Allée Blanche, the Glacier de Miage, forming the opposite side of that of the same name in the valley of Montjoie, and the Glacier de la Brenva. In the Piedmontese valley of Ferret there are the Glacier of Mont Frety, that of Entrèves, the Glacier de Rochefort, the Glacier de la Grande Jorasse, the Glacier de Triolet, and the Glacier of Mondolent. The glaciers in the Swiss valley of Ferret are not of great size; and the only other remarkable one is that of Trient, which stretches northward between the Col de la Forclaz and the Col de Balme. There are also several glaciers in the centre of the mountain group; the principal of which is the Mer de Glace, which forms the upper portion of the Glacier des Bois. The height of Mont Blanc is 15,744 feet above the level of the sea; and on the S. side it rises 11,700 feet almost perpendicularly from the Allée Blanche. Its appearance from this side, accordingly, is much more imposing than when seen from Chamouni, as the acclivity consists entirely of steep and rugged rocks on which no snow lies. (See ALPS.)

MONTBLANCH, a town of Spain, in the province of Tarragona, and 19 miles N.W. of the town of that name. It has a town-house, several churches and schools, an hospital, and a prison. There are distilleries, tanneries, cotton factories, flour and oil mills; and some trade is carried on in wine, brandy, and fruits. Pop. 4200.

MONTBRISON, a town of France, capital of the department of Loire, is situated at the foot of a high and steep rock, on the Vizézy, 37 miles W.S.W. of Lyons. The streets are narrow and crooked, and the houses poor and ill built. The town was formerly fortified; but the walls are now replaced by fine boulevards. It has a Gothic cathedral of the thirteenth century, a court-house, a college, and several schools. Manufactures and trade are carried on to a very trifling extent. Pop. (1851) 6435.

MONT-DE-MARSAN, a town of France, capital of the department of Landes, is situated on a sandy plain, at the junction of the Midon and Douze, which form the Midouze, 63 miles S. of Bordeaux. The streets are broad, regular, well paved, and clean, and contain several fountains. The principal buildings are,—the church, town-hall, court-house, college, theatre, barracks, and prison. There are also public baths, and a public library. Manufactures of sail-cloth, blankets, leather, and brandy, are carried on; and some trade in wine, brandy, oil, wool, and the produce of the neighbouring country. Pop. (1851) 4463.

MONTE CHIARO, a town of Lombardy, on the left bank of the Chiese, 12 miles S.E. of Brescia. It is walled, and was formerly defended by a castle, of which one tower is all that now remains. There are two churches, and

Mont-
blanch
||
Monte
Chiario.

Montecuculi.

several hospitals. Manufactures of silk are carried on; and there is a considerable trade. Near this town the French gained a victory over the Austrians in 1796. Pop. 6700.

MONTECUCULI, RAIMONDO, *Count de*, Prince of Melfi, and generalissimo of the imperial armies of Germany, was descended from a noble family, and was born at Modena in 1608. He entered the imperial forces as a volunteer, was engaged in the war against the Swedes, and quickly rose through the several grades of rank until he was placed in command of 2000 horse. At the head of these, in 1639 he surprised an army of 10,000 before Numslau in Silesia, cut them to pieces, and took their artillery and baggage. But he was speedily overtaken and captured by General Bannier near Prague. After a captivity of two years, spent in close study of the military art, he returned with renewed eagerness to the scene of war. His reputation as a general was retrieved by the defeat of Wrangel at Triebel in 1647. On the peace of Westphalia in 1648, he visited his native duchy; but being so unfortunate as to kill one of his dearest friends, Count Manzani, in a tournament held in honour of the marriage of Duke Francesco I., he hastened his return to Germany. His next expedition was against Prince Ragotski and the Swedes, who, in 1657, were threatening to drive John Casimir, King of Poland, from his kingdom. No sooner had he forced these to conclude a treaty, than he was despatched to relieve the King of Denmark from the Swedish force that was besieging his capital. In this enterprise he continued to experience his usual success until peace was re-established in the north by the death of Charles Gustavus, King of Sweden. He was then sent to check the advance of the Turks into Hungary. At the head of a very inferior force, he continued, by the rapidity of his movements, to baffle all the projects of the grand vizier, until, receiving reinforcements from the French, he came forth boldly into a fair field of battle, and finished the war in 1664 by the brilliant victory of St Gothard. Montecuculi was reserved for achievements still greater. On the outbreak of the war with France in 1673, he was placed at the head of the imperial troops, and contrived to effect a junction with the Prince of Orange, in spite of the manœuvres of the great general Turenne. In the following year the elector of Brandenburg was chosen to supersede him. But it was soon manifest that none but Montecuculi could cope with Turenne: he was therefore reinstalled in the supreme command in 1675. Then began a series of manœuvres and counter-manœuvres more glorious than an equal number of victories. For four months these two generals continued to follow each other, to watch every movement, and to be ever on the alert to seize the slightest advantage. Yet endurance, rapidity, and stratagem were all tried in vain, and could not affect the equality of the contest. Each divined the purposes of the other by supposing what he himself would have done in his position; and no sooner had the one begun to execute any plan than he found that he had been anticipated and thwarted by his opponent. At length the scarcity of provisions rendered it necessary for both parties that a battle should be risked. Turenne was already reconnoitring the ground, when a random ball from a cannon shot him dead, to the deep regret of the magnanimous general whom he had been ready to attack. His place was taken by the Prince of Condé. But not even that great commander could out-manœuvre Montecuculi; and the war was closed without any decisive action. Montecuculi had now finished his last and most glorious campaign. He spent the remainder of his life in the enjoyment of the distinction and honours which his great deeds had won, and in promoting the cause of learning and science. He died at Lintz in October 1681. The military memoirs which he wrote show how profoundly skilled he was in his profession. They were published in Italian at Cologne in 1704,

and in Latin at Vienna in 1718. A French translation, with a Life of the author, appeared at Amsterdam in 1752.

MONTECUCULI, *Sebastiano di*, the alleged poisoner of the eldest son of Francis I., was a gentleman of Ferrara, and was originally in the service of the Emperor Charles V. He came to France in the suite of Catherine de Medici, and was appointed cup-bearer to the Dauphin. It was in this capacity that he accompanied the crown prince on a journey up the Rhone in the midsummer of 1536. While halting at Tournus, the Dauphin, in the midst of a game at tennis, became over-heated, and commanded his cup-bearer to give him a draught of cold water. He drank it off with great avidity, dropped down sick, and expired in a quarter of an hour. Montecuculi was immediately suspected of having poisoned him. His knowledge of medicine, and the fact that a treatise on poisons was found in his possession, confirmed the suspicion. He was therefore examined at Lyons in the usual manner of the day, and a wavering confession was wrung from him by torture. At one time he affirmed that he had been employed to perpetrate the crime by two of the generals of Charles V.; at another time he shifted the accusation on Catherine de Medici. But as he could adduce no facts in proof of either of these charges, he was dragged on a hurdle to the scaffold and executed. The infuriated populace tore his still quivering limbs into a thousand pieces, and threw them into the Rhone. Yet since that time historians have generally agreed in thinking that the Dauphin died of pleurisy, and that Montecuculi was innocent.

MONTEFIASCONI, a town of Italy, in the Papal States, situated on a hill, 9 miles N.N.W. of Viterbo, and 54 N.N.W. of Rome. The only public buildings are a cathedral and a few convents. Some remains have been found here of an ancient Etruscan city, the place of which is occupied by the modern town. The wine of the vicinity is reckoned of fine quality. Pop. 4800.

MONTEFORTE, a town of Naples, province of Principato Ultra, 5 miles W.S.W. of Avellino. It is situated at the foot of a hill, on which stand the remains of a castle formerly the residence of the family of De Montfort, who thence derived their name. The ruins are very picturesque; and from them a fine view of the neighbouring country may be obtained. Pop. 4000.

MONTEGO, a town of Jamaica, capital of Cornwall county, is situated on a bay of the same name, on the N. coast of the island, 17 miles W. of Falmouth. The town is defended by a battery; and the harbour is protected by a breakwater, but is exposed towards the N. There is a considerable trade carried on here. Pop. 4000.

MONTELEONE, a town of Naples, in the province of Calabria Ultra II., in a lofty position, 15 miles N.E. of Nicotera. Its imposing appearance is heightened by its castle, which overlooks the town. The town itself is irregularly and meanly built, chiefly of wood, and is badly paved. There are four churches, with some fine paintings; a royal college; and a court of commerce. The inhabitants are chiefly engaged in the tunny fishery; but there are also some silk-mills; and a considerable trade is carried on. N. of the town, and on the coast, stands the village of S. Pietro di Vivona, where there are some remains of the harbour of Hipponium or Vibo, a city of considerable importance in ancient times. It was originally a colony from the Epizephyrian Locrians, on the other side of the peninsula of Bruttium; but was taken B.C. 389 by Dionysius of Syracuse, who transported the people to that town. Ten years later they were restored by the Carthaginians; but soon afterwards the town fell into the hands of the Bruttians, in whose possession it remained till conquered by the Romans. A colony was established here by the latter in 192 B.C., and the city became one of the most flourishing in this part of Italy. It had large dockyards for ship-building, and was

Montecuculi
||

Monte-
limart
||
Monte-
negro.

conveniently situated for trade both by land and by sea. The ancient town probably stood on the same site as the modern, which is not older than the thirteenth century; but there are no ancient remains to be seen. Pop. 6630.

MONTELMART, a town of France, capital of an arrondissement of the same name, in the department of Drome, is situated at the confluence of the Roubion and the Jabron, 26 miles S. of Valence. The town is defended by Gothic walls, is entered by four gates, and has a castle standing on an eminence in the centre. The houses are well built, and the streets broad and paved with basalt. It derives its name, Monteil d'Adhemar (Mons Adhemari), from an ancient noble family who had possessions here as early as the time of Charlemagne. Montelimart was one of the first towns of France to adopt the Reformed doctrines; and is noted in the civil wars of the Reformation. It has a court of primary instance, and a communal college. Manufactures of silk, leather, hosiery, tiles, &c., are carried on; and the place is famed for a sort of cake made of almonds and honey. Some trade is carried on in these articles, as well as in cattle, corn, &c. Pop. (1851) 8632.

MONTEN, DIETRICH, an eminent battle-painter, was born at Düsseldorf in 1799. The love of his art seems to have been strong from his earliest boyhood. The descriptions of warlike encounters in Homer, Tasso, and Ariosto were the favourite readings of his school-days, and furnished subjects for his first attempts in sketching. That he might become thoroughly intimate with military scenes, he volunteered into the Prussian army in 1828, and served for a year. The next two years were devoted to study in the Academy of Arts in his native town. He then placed himself under the tuition of Peter Hess at Munich, and with the aid of that great battle-painter began to develop his own peculiar style of art. His pictures were executed with a rapidity that left no time for faithful design and elaborate finish. Yet they were full of spirited figures, boldly drawn, and strikingly coloured. In 1827 they had obtained for him the patronage of the painter Cornelius, and of Ludwig I., King of Bavaria. By the former he was employed to execute on the arcade of the Hofgarten three frescoes, representing the scenes from Bavarian history of "The Storming of the Turkish Entrenchment at Belgrade in 1717," "The Battle of Arcis-sur-Aube," and "The Granting of the Bavarian Constitution by Maximilian Joseph I. in 1818." For the latter he painted "The Battle of Saarbrück," and "The Departure of the Poles from their Fatherland." Among his other important historical pieces are "The Death of Gustavus Adolphus," and "The Great Camp in 1838 at Augsburg." Monten died in 1843. (See Bryan's *Dictionary of Painters and Engravers*.)

MONTENEGRO (called by the natives *Zernagora*, and by the Turks *Karadagh*, all which names are derived from the dark forests with which the mountains are covered) is a small state in European Turkey, tributary to the Porte, but virtually independent. It extends from 42. 10. to 42. 56. N. Lat.; and from 18. 41. to 20. 22. E. Long.; and is bounded on the N. by Herzegovina, E. and S. by Albania, and W. by Dalmatia. Area about 1450 square miles. This country consists for the most part of a mass of mountains, forming a part of the Dinarian Alps. The slope towards the sea is very steep; so that there are no rivers of any size on that side, and very little vegetation is found on the rocky acclivities. The lowest parts of this mountainous district are probably more than 2000 feet in elevation, and many of the higher summits rise upwards of 5000 feet above the sea. The interior is intersected with numerous ridges, forming valleys, which, however, are of no great size. Towards the E. the mountains diminish in height, till they are lost in the plain of the Moratsha; and the access to the high lands from this side lies through several narrow gorges. The Moratsha is the only river of any

Monte-
negro.

importance in Montenegro; it flows southward, and falls into the Lake of Skutari, which is situated in Albania, on the confines of Montenegro. The climate is healthy, but cold, owing to the elevated position of the country. The winter is long, and the spring and autumn are often very severe. Owing to the configuration of the country, there are few streams or rivers, and wells do not occur in large numbers; so that the inhabitants are obliged to collect the rain-water in cisterns to supply their wants. Except in a few well-watered spots, the fertility of the soil is not very great; and the ground is not largely cultivated. Indian corn, potatoes, cabbages, and other vegetables are raised; but the inhabitants depend for support chiefly on the live stock which they rear. Sheep, goats, and pigs are numerous, but there are few horses or cattle. Most of the mountains are covered with forests, chiefly consisting of oak and beech, which, though they do not attain their full height on the higher elevations, are often of great size in the lower regions. The Venetian sumach, a shrub, the wood of which is largely used in tanning, is found here in great abundance, and forms an important article of trade. The Montenegrins, from fear of invasion, have made no roads in their country; and internal communication is carried on by means of footpaths impassable for beasts of burden. A good deal of trade is carried on with the inhabitants of Cattaro in Dalmatia; but the Montenegrins are not allowed to carry on any intercourse with the neighbouring Turkish towns. They export live stock, smoked mutton, bacon, cheese, tallow, sheepskins, wool, &c., as well as the sumach wood and firewood; while they import wine, spirits, oil, salt, gunpowder, fire-arms, and other manufactured articles. The average value of the annual exports to Austria is L.1392, and that of the imports from that country L.434. Montenegro proper consists of four *nahias* or cantons—Katunska, Rietshka, Zernnitska, and Lieshanska; but besides these there are some other tribes which belong to the confederation. These also are divided into four cantons, called *berdas*, distinguished by the names of Bielopovlitska, Piperska, Kutshka, and Moratshka; and the inhabitants are called Berdiani, to distinguish them from the Montenegrins proper, or Zernagorzi. The government is in the hands of a vladika or prince, residing at Zetlinie; and the office is hereditary in the male line. The religion of the people is that of the Greek church; of which the vladika was formerly a bishop, uniting the supreme civil and ecclesiastical authority in his own person; but since 1851 these offices have been separated. There is a Senate, or council of elders, consisting of 12 members, to assist the prince. The people are tall, hardy, and athletic. They have great hospitality and a strong feeling of patriotism; but their mode of warfare is barbarous and unsparing, and they are constantly making plundering forays into the neighbouring districts. Their system of defence, when their country is invaded, consists of posting sharpshooters in various positions in the mountains, and enticing the invaders into these fastnesses, where they are gradually shot down by the unerring aim of the Montenegrin riflemen. When out of their own country, however, these mountaineers cannot stand against regular troops. The language spoken in Montenegro is a dialect of the Slavonic, the same as that spoken in Servia. Education is in a very low state, and it is thought a great accomplishment to be able to read and write. There are only two schools, one at Zetlinie and one at Dobroskoselo, both of which have been founded since 1841. The Montenegrins were reduced under the dominion of the Turkish empire in the reign of Solyman the Magnificent, and they remained in this condition till the year 1700, when, at the instigation of the Vladika Daniel, all the Mohammedans were put to death, and the country declared independent. In 1712 the inhabitants of the canton of Katunska took up arms in

Montereau
||
Monte
Rosa.

favour of Peter the Great, and defeated a large Turkish army. The remaining three cantons united with that of Katunska in a confederation, after another victory gained over the Turks in 1796; and the tribes of Bielopovlitska and Moratska were added about the beginning of the present century. The last to join the republic was the tribe of Kutshka, which did not do so till 1831. The independence of Montenegro, however, although virtually complete, was never recognised by the Ottoman Porte, nor by any other of the European powers, with the exception of Russia. The emperor of that country took the Montenegrins under his protection, and sent to the vladika an annual remittance of L.4000, to meet the tribute paid to the Sublime Porte. The Austrian government also was always favourable to the independence of Montenegro. In 1851, on the death of the Vladika Pierre Petrovitch, his nephew Daniel, who was appointed by his will to succeed him, refused to assume the office of bishop, and proposed to the Senate of Montenegro that the civil and ecclesiastical power should thenceforth be disjoined. This change in the constitution was approved of by the Senate and by the Emperor of Russia; and the prince, on his return from St Petersburg, was received amid the acclamations of the people. In 1853, in consequence of the seizure by the Montenegrins of the fortress of Zabliak, on the Lake of Skutari, the country was invaded by a Turkish army of 34,000 men, under the command of Omer Pasha; but after gaining a few successes in bloody conflicts, the interference of the Austrian and Russian cabinets induced the Sultan to recall this force, and leave Montenegro in its former state of independence. The population of Montenegro is about 120,000.

MONTÉREAU, or MONTÉREAU-FAUT-YONNE, a town of France, in the department of Seine-et-Marne, is situated at the confluence of the Yonne and the Seine, 12 miles E. of Fontainebleau. It is divided into three parts by the two rivers, which are crossed by bridges, the largest part lying on the left bank of the Yonne. The town is for the most part well built, and has a collegiate church, an hospital, and a town-hall. Manufactures of hosiery, leather, and earthenware are carried on, and there is a considerable trade with Paris in grain, timber, cattle, &c. Montereau is remarkable in history for the murder of the Duke of Burgundy at the bridge over the Seine in 1419, and for the last victory of Napoleon, February 18, 1814. Pop. 4826.

MONTÉREY, a town of Mexico, capital of the state of New Leon, is situated on the Tigre, at the head of an extensive and picturesque valley, 85 miles E. by N. of Saltillo. The town is well built and paved, most of the houses being in the Moorish style, with flat roofs. The climate is mild and healthy, and there are gold, silver, and lead mines in the neighbourhood. Monterey is well fortified, and offered some resistance to the invading army of General Taylor in 1846; but after an assault of three days, it surrendered on honourable terms. Pop. about 13,000.

MONTE ROSA, a mountain of the Pennine Alps, on the borders of Switzerland and Piedmont, is a union of several mountain chains rather than a single summit. Four mountain chains radiate from a centre point, N., S., E., and W., respectively. A ridge of inaccessible mountains extends E. and W., from the Cime de la Pisse on the E. to the Col du Mont Cervin on the W.; and this is intersected at right angles by another chain, extending northwards as far as the Cima di Jazy, and southwards as far as the Col d'Ollen. The centre where these branches unite, called the Signal Kuppe, is not the most elevated point, there being three of greater height on the northern range. The first of these is called the Zumsteinspitze, and is the only one of the three which has been ascended; the second is the Höchste Spitze, or highest of all, which is connected with the former by a narrow and sharp ridge, descending steeply on one side into a tremendous abyss; and the third

is the "Nord-End," which, like the highest, has not yet been ascended. The difference of the height of these four peaks is not, however, more than 200 feet between the highest and the lowest. The height of the highest is 15,158 feet above the sea. The four branches of Monte Rosa inclose between them four glaciers,—viz., that of Macugnana on the N.E., that of Gorner on the N.W., that of Lys on the S.W., and several of less size in the valley of Sesia on the S.E. The geological formation of Monte Rosa is gneiss and mica-slate; and it separates the waters flowing to the Rhone from those which join the Po. (See ALPS.)

MONTE SAN GIULIANO, a town of Sicily, in the province of Trapani, is situated on a mountain 2184 feet high, 5 miles E.N.E. of Trapani. It has a large number of churches and convents, and an hospital. The mountain was in ancient times called Eryx, and had a temple of Venus on the top, founded, according to tradition, by Æneas. This is now replaced by a Saracen castle. The town of Eryx belonged to a Sicilian tribe called Elymi, but afterwards fell into the hands of the Carthaginians. Though taken by Pyrrhus in 378, it was regained by the Carthaginians, who abandoned it in the first Punic war. It does not seem to have been restored by the Romans. Pop. 6600.

MONTESQUIEU, CHARLES DE SECONDAT, *Baron de la Brède et de*, was descended from an ancient and noble family of Guienne, and was born on the 18th of January 1689, at the castle of La Brède, near Bordeaux, where he passed his early days, and composed those works which have acquired for their author an imperishable reputation. His father having early discovered in him indications of genius, and a promise of future eminence, bestowed the utmost pains on his education, which appears to have been conducted with equal judgment and success; and being destined for the magistracy, he employed the energies of his active mind in studying the immense collection of the different codes, and in endeavouring to detect the motives, and unravel the complicated relations, of the obscure or contradictory laws contained in them. His taste for this study was insatiable; and if it proved the source of his future glory, it was also that of his greatest happiness. He has himself stated, that he never had to reproach himself with an hour of reading wasted or misspent. When exhausted with his arid labours upon jurisprudence, he recruited his mind with books of history and travels, and with the productions of the classical ages of Greece and Rome. Enchanted, as he says, with antiquity, he at the age of twenty composed a work, in the form of letters, wherein he sought to prove that the idolatry of the pagans did not appear to deserve eternal damnation; but this first production of his genius he wisely abstained from giving to the world. On the 24th of February 1714 he was received as counsellor to the Parliament of Bordeaux; and on the 13th of July 1716 he was, through the influence of his paternal uncle, named president *à mortier*. The same year he was admitted into the Academy of Bordeaux, which had been recently founded by a number of persons possessing a common taste for music and works of entertainment. Conceiving, however, that its object was too limited, and desirous to extend the sphere of its utility, he undertook to convert this coterie of wits into a learned society; and his views in this respect were warmly seconded by the Duke of La Force, who founded a prize, and held out several other inducements to the cultivation of science. As a member of this learned association, he contributed his contingent of memoirs or communications, chiefly on subjects connected with natural history, a species of study for which he had a particular taste. But his physical constitution disqualified him for that minute observation which is essential to the successful prosecution of this particular science. He was not only short-sighted, but his vision was weak:

Monte San
Giuliano
||
Montesquieu.

Montesquieu.

and this infirmity increased so much with time, that towards the close of his life he became almost blind. It may also be observed that, at the period when Montesquieu applied himself to natural history, the fundamental principles of that science had not yet been established. In 1719 he circulated, by means of the journals, an *Histoire Physique de la Terre ancienne et moderne*; and he read successively to the Academy of Bordeaux a dissertation *Sur la Politique des Romains dans la Religion*, an *Eloge du Duc de la Force*, and a *Vie du Maréchal de Berwick*, a production which in several points recalls the manner of Tacitus.

Montesquieu, however, was by no means in haste to appear before the public in the character of author. He preferred waiting until his faculties were ripened by time and matured by reflection; nor was it until the year 1721 that he entered upon his literary career, by the publication of the *Lettres Persanes*, the first idea of which seems to have been borrowed from the *Siamois* of the *Amusemens Sérieux et Comiques* of Dufresnoy, though, in works of genius, the primary conception is of little moment compared with the execution. The success of the *Lettres Persanes*, and the influence which they exercised, were unparalleled. This is to be ascribed to two causes; the circumstances of the period at which the book appeared, and the form into which it was cast. On the death of Louis XIV. libertinism succeeded to devotion, effrontery to hypocrisy, familiarity to respect, and audacity to submission. The liberty of saying or writing anything with impunity led men to examine and to combat all that had been agreed to without opposition, or even assented to with enthusiasm. In the midst of this general effervescence appeared the book of the *Lettres Persanes*. From the shape into which it was cast, it had all the attractions of a romance; it abounded in voluptuous details, which flattered the taste of the age for pleasure, and in irreligious sarcasms, which gratified its tendency to infidelity; and it treated with contempt Louis XIV. and his reign, which people now sought to depreciate. But it must nevertheless be admitted, that, with all these faults, the book displays an ardent love for the welfare of mankind; a courageous zeal for the triumph of reason and virtue; luminous views upon commerce, public law, criminal jurisprudence, and the dearest interests of nations; a penetrating insight into the vices of society, as well as those of governments; and, generally, strong evidence of profound reflection, which takes the reader the more by surprise that it seems to be the constant object of the author to disguise it under the mask of frivolity. Its principal attraction, however, and that which won the suffrages of all, consisted in the keen, animated, sprightly, satire of French manners and caprices, and in a style always lively, sparkling, full of happy innuendos and unexpected contrasts, the pointed irony of which sometimes rose to the most energetic eloquence.

Four years after the publication of the *Lettres Persanes*, Montesquieu caused to be printed separately, in 1725, the *Temple de Gnide*, an ingenious trifle, though cold and without interest, being equally devoid of easy wit or natural grace, and which Madame du Deffand happily called the "Apocalypse of Gallantry." The same year, at the opening of the Parliament of Bordeaux, he delivered a discourse on the duties of magistrates, advocates, attorneys, and all those connected with the administration of law, which, though but little noticed, is written in a fluent, impassioned style, different from the ordinary manner of Montesquieu, and in that vein of eloquence which addresses itself more to the sentiments than to the reason of men. In 1726 he sold his office and withdrew from the magistracy, the duties of which he had so well described. The desire to regain his freedom, and apply himself entirely to philosophy and letters, was no doubt one of his motives; but the principal cause of this determination seems to have been a sense of

Montesquieu.

inadequacy to fill the situation in which he was placed. He informs us, indeed, that his whole merit as president consisted in rectitude of purpose and understanding sufficiently the questions themselves; but that he had never been able to master the forms of procedure, although he had applied himself to the subject.

Being now at liberty to devote himself exclusively to philosophy and letters, he presented himself as a candidate for the place in the French Academy vacant by the death of M. de Sacy; but Cardinal Fleury wrote to the Academy that the King had declared he would not give his approbation to the author of a work containing impious sarcasms against religion. Montesquieu, however, though at once amazed and offended by the refusal of the King and his minister, contrived, by a device more dexterous than candid, to propitiate the cardinal. He asserted his claim with firmness, yet disavowed those letters of the book which formed a legitimate ground of objection against him. The King was appeased by the intervention of the minister, and on the 24th of January 1728 he was received into the Academy, on which occasion he delivered an inaugural discourse, which appears amongst his printed works. Montesquieu having accomplished this object, resolved to travel, and in the course of his peregrinations visited almost all the countries of Europe. He proceeded first to Vienna, where he often saw Prince Eugene; he then passed into Hungary, whence he journeyed to Italy, and at Venice became acquainted with John Law of Lauriston, who, from the height of grandeur, wealth, and celebrity, had fallen into obscurity, neglect, and poverty; and also with the Comte de Bonnevol, who had as yet only gone through part of the cycle of his romantic adventures. From Venice he proceeded to Rome, where he became acquainted with Cardinal Corsini, afterwards Clement XII., and with Cardinal Polignac, author of the *Anti-Lucrèce*. He next visited Genoa, but having met with a cold reception there, he soothed his ill-humour by writing some satirical stanzas, which, however, he did not think fit to print. From Italy he passed into Switzerland, and traversing the different countries watered by the Rhine, stopped some time in Holland, where he met Lord Chesterfield, with whom he had become acquainted at Venice. He then visited England, where he resided about two years, was admitted a member of the Royal Society, and treated with marked distinction by Queen Caroline. On his return to his own country, he retired to his castle at La Brède, where he resumed his favourite pursuits. He had either before or during his travels caused to be printed in Holland a little work entitled *Réflexions sur la Monarchie universelle*, which is now but little known, and extremely rare, though it is referred to by the author himself in a passage of the *Esprit des Loix* (l. xxi., c. 22). The object of this piece was to prove that, in the actual state of the modern nations of Europe, it is impossible even for the ablest and most ambitious of sovereigns to establish a universal monarchy.

After two years spent in his retreat at La Brède, Montesquieu published in 1734 his *Considérations sur les Causes de la Grandeur et de la Décadence des Romains*; a work which, if not the most remarkable, is perhaps the most finished of all his productions, and in which he had to enter into competition with several eminent men, both amongst the ancients and the moderns, particularly Polybius, Machiavelli, Saint-Evremond, and Bossuet. But Montesquieu was the first writer who grappled with this great subject in all its details, and who compared all the facts with laborious sagacity. He overlooked none which could afford matter for reflection, or warrant any inference of importance, and yet he managed to compress the whole into a volume of moderate size. The *Dialogue de Sylla et d'Eucrate*, which is subjoined to this work, and may be considered as forming part of it, is one of those productions in which

Montesquieu.

Montesquieu has displayed the greatest eloquence; and with this may be classed another piece not less remarkable, namely, *Lysimaque*, in which he has delineated, in a manner altogether sublime, that system of stoicism which raised man above the ordinary weaknesses of his nature, and enabled him to brave with joy, and even with pride, the cruelties of tyrants and the iniquities of fortune.

The *Considerations on the Grandeur and Decline of the Romans* make us acquainted with the history of a single people; but Montesquieu had long been engaged in studying that of all other nations, in discovering the causes of those revolutions which had successively changed the face of the world, and in investigating those laws and customs which had contributed to their prosperity or decline. The success of the treatise on the Roman people, which in some sort formed only a detached portion of the vast plan he had conceived, served to increase his ardour in the execution of so great an undertaking, to the completion of which fourteen more years of incessant labour were devoted. Sometimes he thought that he advanced rapidly, and would speedily accomplish his design; at other times he appeared to recede, and to become perplexed by the immensity and complication of the subject. At length, after twenty years of unremitting application, he had the satisfaction to put the last hand to a production upon which he had expended so much anxious labour and meditation, and which he entitled *L'Esprit des Loix*. But before sending this work to the press, he judged it prudent to consult one of his intimate friends, whose talents and knowledge he respected; and with this view he sent his manuscript to Helvetius. The latter, however, was so little satisfied with the production after perusal, and so much alarmed for the danger to which the reputation of Montesquieu would be exposed by the publication of a work which he considered as so defective, that at first he did not venture to express what he thought of it, and solicited the author's permission to communicate the manuscript to a common friend, Saurin, the author of *Spartacus*. The latter coincided in opinion with Helvetius, and both agreed that, by the publication of this book, the celebrated author of the *Lettres Persanes* would injure his reputation, and lower himself in the estimation of the world. After some hesitation, this extraordinary judgment was communicated to Montesquieu, accompanied with an earnest entreaty on the part of both that he would subject the whole to careful revision, and upon no account publish the work in the crude and imperfect state in which it then appeared. The strange counsels of these friends, however, had so little influence on Montesquieu, that he sent the manuscript to the press without altering a word, prefixing this epigraph, "*Prolem sine matre creatam*," to indicate that his work had no model; and, as if to mark still more strongly how little he was moved by their unfavourable judgment, he congratulated himself in his preface on having produced a work which was not altogether destitute of genius. Nor did the result disappoint the just expectations he had formed. Its success was in fact so great, than in little more than a year and a half after its publication, it had gone through twenty-two editions, and been translated into, almost every language of Europe. The *Esprit des Loix* appeared about the middle of the year 1748, and before the end of the year 1750 its reputation was universal.

If the *Spirit of Laws*, however, was much read, much admired, and much praised, the work, like all those which have produced a great impression, was also much criticised. Madame du Deffand said of it, that it was not *l'esprit des loix*, but *de l'esprit sur les loix*, a saying which had just that degree of truth which gives currency to an epigram. But the work was not of a kind likely to interest the epigrammatic mind at all. It was written with quite a different aim, and has had quite a different reputation now that men have had time to judge of its merits. Its author addressed himself to

Montesquieu.

men of reason and experience, to statesmen and thinkers in general. Those political problems which had been hitherto shaded by uncertainty, or obscured by ignorance, and with which the world had been occupied previous to his time, Montesquieu either solved or placed in a clear light for subsequent investigators. And although not a few of the hostile criticisms with which his work was assailed appeared to be well founded, the reputation of Montesquieu was greatly enhanced by the publication of the *Spirit of Laws*; and it may be said with truth, that this work alone would have been sufficient to insure him lasting renown, and to constitute a noble monument of his genius, sagacity, and wisdom. For an estimate of the relative merit and true historical position of the *Esprit des Loix*, in establishing just ideas of jurisprudence, see the *First Preliminary Dissertation* (part i., sect. iii.)

Montesquieu had resolved not to reply to any of the criticisms which might be made on the *Esprit des Loix*; but the attacks of an anonymous author, who, in a journal called *Nouvelles Ecclésiastiques*, had, amongst other things, represented him as an atheist, induced him to deviate from this resolution. In the *Lettres Persanes* he had treated the Christian religion with too much levity; but afterwards, when his mind was fully matured by age, study, and reflection, he had seen cause to alter his views; and hence in the *Esprit des Loix*, he recommends Christianity in expressive terms, not only as the most perfect of all religious systems, but also as the most powerful support of the whole social system. He therefore deemed it of importance to repel the calumnious insinuations of the ecclesiastical journalist, and at the same time he wished to refute by anticipation the theologians of the Sorbonne, who, being dissatisfied with some passages in the *Esprit des Loix*, were proceeding to condemn the work. It was with this double purpose that he wrote his *Défense*, which may be considered as a model of solid discussion, light pleasantry, and contemptuous moderation. "What pleases me in my *Défense*," said he, "is not seeing the venerable theologians gravelled; it is seeing them laid gently upon their backs." But he took no notice whatever of a crowd of *brochures*, filled with absurd criticisms or gross abuse, which appeared against the *Spirit of Laws*. "The public," said he, "avenge me on the one by their contempt, and on the other by their indignation."

The appearance of a book like the *Spirit of Laws*, naturally formed an epoch in political and literary history; but its effect was different in different countries, being greatest in Britain, where it obtained a reputation, which has since continued to increase, and least in France, where its influence was and still is but small. This may be accounted for partly from the different circumstances in which these countries were respectively placed, and partly also from the fact that, while Montesquieu pointed out the hazards to which the British constitution was exposed from the incessant conflicts of a tyrannical oligarchy and a turbulent democracy, he had confined his researches to the dark ages of the French monarchy, in regard to which his efforts were doubtful, and his conclusions disputed. But if his work did not prove as useful to his country as he had hoped, the reputation which he had acquired in his lifetime far exceeded that which men of letters can ordinarily aspire to obtain. He was considered throughout all Europe as the legislator of nations, and the founder of the philosophy of jurisprudence and politics. But, far from being dazzled by this high reputation, he continued to live like a sage, and to enjoy the society of his friends, dividing his time between his castle of La Brède and Paris,—that is, between study and the world. In the country, he occupied himself with gardening and agricultural improvements, and, though jealous of his seigniorial rights, was much beloved by the peasantry, whose comfort and happiness it was his

Montesquieu.

object to promote. In the capital he was always a welcome guest, although simple and somewhat negligent in his dress, as well as in his conversation. He was always disposed to render justice to talents, and to relieve merit in distress. One day he received from Henry Sully, an English artist, who had greatly contributed to improve horology in France, the following letter:—"I am tempted to hang myself, but I believe nevertheless that I should not do so if I had an hundred crowns." To this Montesquieu immediately replied,—"I send you an hundred crowns, my dear Sully; do not hang yourself, and come to see me."

Although in some of his opinions Montesquieu sympathized with the philosophers of his day, yet he loved neither the proselytism of impiety nor the excesses of the spirit of cabal. Nor was this the only cause of his estrangement from Voltaire. Being in a great measure insensible to the charms of verse, he thought the reputation of that celebrated man usurped, and did not hesitate to express his opinion to that effect; whilst Voltaire, on the other hand, was by no means sparing in malignant reflections and bitter criticisms. In fact, they mutually accused each other of having too much wit, and frequently abusing it in their writings. But Voltaire had an exquisite sense of literary merit, which triumphed over his strongest antipathies; and, under its benign influence, he did justice to the author of the *Spirit of Laws*, by observing, that "when the human race had lost their titles, Montesquieu found and restored them;" a fine thought, notwithstanding the epigrammatic form in which it is expressed. But whatever might be his sentiments in regard to Voltaire and the other men of letters of his time, it was only in conversation, or in the intimacy of familiar intercourse, that he allowed the secret of his opinions to escape; he never wrote against any of his contemporaries, and conducted himself with a dignity and wisdom which were the effect of the moderation of his passions, as well as the result of reflection. At the solicitation of D'Alembert and the Chevalier de Jaucourt, Montesquieu, having completed the *Esprit des Loix*, consented to write for the *Encyclopédie*, and composed for that work the *Essai sur le Gout*, some inedited chapters of which were afterwards published in the *Archives Littéraires* (tom. ii., p. 301).

It appears that soon after the publication of the *Esprit des Loix*, his physical strength diminished rapidly, and no longer corresponded to his ardour in literary pursuits. He had conceived the design, as he informs us in his journal, of giving greater extension and depth to several parts of the *Spirit of Laws*; but he found that he had become incapable of carrying his intention into effect. "Mes lectures," says he, "m'ont affaibli les yeux; et il me semble que ce qu'il me reste encore de lumière, n'est que l'aurore du jour où ils se fermeront pour jamais." And in fact he died soon afterwards, on the 10th of February 1755, at the age of sixty-six; that is, only seven years after the publication of his great work. He was attacked at Paris with a violent inflammatory fever, which, in spite of every effort to arrest its progress, carried him off after an illness of about a fortnight. But the benignity of his character sustained him to the last moment; no complaint, no sign of impatience, escaped him. He knew from the first that he was in imminent danger, and occasionally asked his physicians, "Comment va l'espérance à la crainte?" The Jesuits tried to gain him over in his last moments, and, with this view, sent to him Fathers Routh and Castel, who were accused of exercising their ministry with undue importunity. He observed to them, "I have always respected religion; the morality of the gospel is the finest present which God has made to men." As the Jesuits pressed him to put into their hands the corrections he had made on the *Lettres Persanes*, that the irreligious passages might be effaced, he refused to comply with their request; but he afterwards

placed the manuscript in the hands of the Duchess of Aiguillon and Madame Dupré de Saint-Maur, saying, "I wish to sacrifice everything to religion, but nothing to the Jesuits; consult with my friends, and decide if this ought to appear." Nevertheless, he received the viaticum from the hands of the parish priest, who, at the same time, observed to him, "Monsieur, vous comprenez combien Dieu est grand;" "Oui," replied the dying philosopher, "et combien les hommes sont petits."

Montesquieu left a great number of manuscripts. They consist of,—1. A little romance entitled *Le Métempsychose*, by no means worthy of the author of the *Lettres Persanes*; 2. Morceaux qui n'ont put entrer dans *l'Esprit des Loix*, et qui peuvent former des dissertations particulières, amongst which are one on *Paternal Authority*, another on *Verbal Obligations*, and a third on *Successions*; 3. Three large volumes in quarto, bound, consisting of extracts made by him in the course of his reading, with reflections annexed. In these volumes there are several original pieces of considerable extent, particularly a sort of introduction to the History of Louis XI., which is considered as equal to anything that Montesquieu ever wrote. He is said to have written an account of his travels, which if it exists at all, must be in a very imperfect state; and as to the *Notes sur l'Angleterre*, inserted in some of the last editions of his works, we know not whether they were extracted from the materials which he had prepared for the *Rélation de ses Voyages*.

Among a vast number of editors and commentators on the works of Montesquieu, we may cite the following distinguished names:—Voltaire, Condorcet, Helvetius, D'Alembert, Mably, La Harpe, Destutt de Tracy, and Villemain.

(J. B.—E.)

MONTEVERDE, CLAUDIO, a remarkable Italian composer, was born at Cremona about the year 1565. He entered into the service of the Duke of Mantua as a performer on the viol, and received lessons in counterpoint from Marc Antonio Ingegneri, the Duke's chapel-master, to whose office he afterwards succeeded about 1604. On the 19th of August 1613 he was appointed chapel-master of St Mark's at Venice, and held that place till his death in the autumn of 1649. The first two books of his Madrigals are so incorrectly written as to prove that his study of counterpoint had not at that time (1587) been very profound. In his third book of Madrigals he appeared to more advantage; and the ideas which had emanated from Florentine musicians regarding the necessity of expressing the sense of the words in vocal music, had evidently stimulated his genius to explore new paths of composition. Regarding the harmonic novelties and the new tonality introduced by Monteverde, see the articles MUSIC and TONALITY in the present work.

(G. F. G.)

MONTE-VIDEO, or SAN FELIPE DE MONTE-VIDEO, the capital of Uruguay in South America, is situated on the northern shore of the estuary of the La Plata, 130 miles E.S.E. of Buenos Ayres, S. Lat. 34. 53., W. Long. 56. 16. It stands on a gentle eminence at the extremity of a small promontory which forms the east side of the harbour, a bay 4 miles in length by 2 in breadth. The houses are well built, and floored with unbaked bricks. They are for the most part only one storey high, and have flat roofs. The streets are broad, regular, and well paved. There are no great public buildings, except the cathedral, a handsome stone edifice, and the town-hall. Monte-Video is surrounded by walls, which are mounted with guns; and there is also a citadel. The climate is healthy, and the soil of the surrounding country rich and productive; but water is very scarce, and can only be obtained by wells dug on the seashore, or by collecting the rain-water in cisterns. The harbour is shallow, varying from 14 to 19 feet in depth; but the bottom is soft, and does not injure the vessels that

Monte-
verde
||
Monte-
Video.

Mont-
faucou
||
Mont-
gomery.

may run aground. The winds from the S.S.W. blow into the harbour and cause a considerable swell. The number of vessels that entered the harbour in 1856, including the coasting trade, was 1220, and their tonnage 149,567; while those that cleared were 978, and their tonnage 141,131. The trade of Monte-Video is very considerable; the exports, consisting of wool, hides, tallow, salt beef, &c.; and the imports of cotton and woollen fabrics, hardware, wine, provisions, &c. A line of steamers was established in 1856 between Monte-Video and Genoa; and there is also another, supported by the government of Brazil, between this place and Rio Janeiro. Pop. about 12,000.

MONTFAUCON, BERNARD DE, an eminent critical and antiquarian writer, was descended from a noble and ancient family, and was born at the chateau of Soulage, in Languedoc, in January 1655. After a short attendance at the college of Limoux, he was left to educate himself, and he passed his days in the library of the family castle, Roque-tailade, perusing books in different languages and on almost every variety of subject. During his historical readings he had become partial to a soldier's life. Accordingly, he enlisted as a volunteer in the regiment of Languedoc in 1673, and served two campaigns in Germany under Marshal Turenne. But grief for the loss of his parents rendered him weary of the world, and induced him in 1675 to assume the garb of the Benedictines in the congregation of St Maur. The rest of his biography is little else than a recital of his many important works. He now consecrated his leisure to the study of Greek and the Oriental languages. His enthusiastic devotion to learning, supported by a robust and well-regulated constitution, carried him rapidly through his extensive field of labour and research, and the result of his studies issued in quick succession from the press. The work that established Montfaucon's reputation was a new edition of Athanasius, in Latin and Greek, 3 vols. folio, 1698. His next great undertaking was the editing of the works of Chrysostom. In the prosecution of this task he spent three years in Italy, visiting the principal cities, and consulting the manuscripts in the principal libraries. In 1718, sixteen years after his return, his *Chrysostom* began to be published; and in 1738 it was completed in 13 folio volumes. It is still considered the best edition of that eloquent father. Montfaucon died in December 1741, at the age of eighty-seven. The most important of his other works are,—*Analecta Græca sive varia Opuscula*, 4to, Paris, 1688; *Diarium Italicum*, 4to, Paris, 1702; *Collectio Nova Patrum Græcorum*, folio, Paris, 1707; *Palæographia Græca, sive de Ortu et Progressu Literarum Græcarum*, folio, Paris, 1708; *Le Livre de Philon de la Vie Contemplative*, 12mo, Paris, 1709; *Bibliotheca Costiniana*, folio, Paris, 1715; *L'Antiquité Expliquée et Représentée en Figures*, 10 vols. folio, Paris, 1719; *Les Monuments de la Monarchie Française*, 5 vols. folio, Paris, 1729–33; and *Bibliotheca Manuscriptorum Nova*, 2 vols. folio, Paris, 1739.

MONTFORT, SIMON DE. See ENGLAND.

MONTGOMERY, ALEXANDER, an old Scottish poet, who flourished in the reign of James VI. The little that is known about his life is involved in doubt. His nickname of "The Highland Knight," which is mentioned by Dempster, seems to indicate his descent, and at the same time confirms, to a certain extent, the generally-received opinion that he was brought up in Argyllshire. He is supposed to have been an officer in the guard of the Regent Morton, a circumstance that may account for his ordinary title of "Captain Alexander Montgomery." His fame as a poet appears to have been great among his contemporaries. James VI. quoted some of his poems in a work entitled *Revels and Cautelis*; and bestowed upon him a pension of 500 merks. But this latter expression of royal favour afterwards led Montgomery into a tedious lawsuit, which

Mont-
gomery.

brought in its train several other evils. His life was thus embittered, and his poetry assumed a tone of complaint and of severe satire against judges and lawyers. His principal work, the allegorical poem of *The Cherry and the Slae*, was published in 1607. Between this date and 1611 the poet is said to have died. Montgomery's entire works were published at Edinburgh in 1822, under the superintendence of Mr David Laing, and with a biographical preface by Dr Irving. His chief characteristics as a poet are a vigorous and lively fancy, a love for rural objects, and a power of versification beyond most of his contemporaries.

MONTGOMERY, James, one of the most popular of the sacred or religious poets of England, was born at Irvine in Ayrshire, on the 4th of November 1771. His parents were Irish—his father a preacher of the Society of United Moravian Brethren. James was designed for the same office, and in his sixth year was placed in the Moravian establishment at Fulneck, near Leeds, where he was as effectually excluded from the world and all its ways as if he had been immured in a Dominican convent. A love of poetry was kindled in him by hearing one of his masters read aloud Blair's *Grave*. He refused to study for the ministry; and both his parents being then dead (they had died in Barbadoes, his father having been sent on a missionary enterprise to the West Indies), the Brethren at Fulneck put James apprentice to a grocer in Mirfield. He disliked the drudgery of the shop, wrote verses, and at length ran away, with three shillings and sixpence in his pocket. After some wayside hardships and wanderings, he got engaged as shop-boy in the pretty Yorkshire village of Wath, where he remained for a twelvemonth. He next removed to London, intent on publishing a volume of poetry; but the Brethren of the Row were as adverse to his poetical ambition as the Brethren of Fulneck; and he was glad to obtain employment from one of the number, Harrison, a well-known publisher, as clerk and assistant. He soon tired of London, and retraced his steps back to Wath, perhaps induced in some degree by recollection of a certain Nancy Wainwright, "one of the Wath beauties, whom, I am afraid," he says, "I sometimes looked at in church more than was proper." The looks came to nothing; and this is the only instance of anything like an approach to gallantry in the long bachelor life of Montgomery. In his twenty-first year he made another and final removal. He went to Sheffield as clerk to Mr Gales, an auctioneer and publisher of a weekly newspaper, the *Sheffield Register*. This paper was liberal in its tone and tendencies, and Mr Gales was marked out as a disaffected man. The whole nation was at that time agitated by the example or by dread of revolutionized France; spies and informers abounded; and local rulers, like the government, were jealous and eager to convict. The Sheffield editor was wrecked in the political storm; the *Register* went down, and in its place the *Iris* came forth, with James Montgomery for its conductor and proprietor. He was now in a congenial and independent position; he had a weekly outlet for all his thoughts and musings, whether in prose or verse; and, though no politician, he had a true poet's love of liberty and hatred of meanness, fraud, or oppression. He was determined to be prudent; he was by nature inoffensive; yet within a twelvemonth, before he had completed his twenty-fifth year, he was twice convicted, fined, and imprisoned for libels. He had printed for a hawker some copies of two old songs that remained in type in the office. One of them related to the destruction of the Bastille in 1789, and was surmounted by a rude woodcut representing Liberty and the British lion. The hawker sold the songs in the streets, ingeniously drawing attention to his wares by crying "straws to sell." The purchaser of a straw, price one halfpenny, obtained a copy of the ballads; and one of the Sheffield constables, acute as Dogberry, smelt treason in this device of the straws, and in the

Montgomery. "effigies" of Liberty and the Lion. The printer was traced; he was found to be the suspected editor of the *Iris*; and Montgomery, after a form of trial, was sentenced to three months' imprisonment in York Castle, and to pay a fine of L.20. His second offence consisted in some reflections on the conduct of a colonel of militia, who had displayed superabundant zeal and recklessness in quelling a street riot. After an extraordinary scene of contradictory evidence, a verdict was given against the publisher of the *Iris*, and he was sent again to York Castle, but for a period of six months, and with the further penalty of a fine of L.30. Such oppression seems almost incredible now; and Montgomery said, that "no man who did not live amidst the delirium of those evil days and that strife of evil tongues, could imagine the bitterness of animosity which infatuated the zealous partisans." In his own case he lived to see it all extinguished. He ultimately found friends among his old opponents—even the fiery militia colonel; but for some years he was neither democratic enough for the wild reformers, nor submissive enough to serve the purposes of the local magnates, and his editorial life was truly a life of martyrdom. He was able to retire from it altogether in the year 1825, and on that occasion a great public banquet, presided over by Viscount Milton, was given him by his townsmen and neighbours, men of all ranks, classes, and distinctions. Politics and political strife were now buried for ever, and there was a long day of warmth and sunshine after the cold blasts of the morning.

The literary career of Montgomery dates from his incarceration in York Castle. He wrote there, and published in 1797, *Prison Amusements*, a series of short poems, which had only a local reputation. In 1805 he issued another poem, *The Ocean*; and in 1806 *The Wanderer of Switzerland, and other Poems*. The last of these volumes had gone through two editions, when it happened to fall into the critical hands of Francis Jeffrey, and received a check which, to the sensitive poet, seemed to threaten nothing less than the annihilation of his hopes and labours. The *Edinburgh Review* denounced the unfortunate volume in a style of such authoritative reprobation as no mortal verse could be expected to survive. The critic, however, proved a bad prophet: the work continued popular because it was really worthy of popularity; and the criticism must be set down as one of those wanton sins against good taste and proper feeling which the *Review* occasionally perpetrated in its nonage, before it had attained to years of discretion. Montgomery's next poetical production was written to commemorate the abolition of the slave-trade, and was entitled *The West Indies*. It is in the heroic couplet of Dryden and Pope, and exhibits the poet's command of that peculiarly English style of verse, the best of all for narrative poetry. In 1813 appeared *The World before the Flood*, also in the same measure; in 1819, *Greenland*, a poem founded on the Moravian mission to that remote territory; and in 1827 *The Pelican Island*, a descriptive poem in blank verse, and which is unquestionably the most original and powerful of all Montgomery's works. Numerous exquisite little pieces from his pen came forth in the annuals and other periodicals; and he collected two volumes of sketches, published under the quaint title of *Prose by a Poet*. In the winter of 1830–31 he delivered a course of lectures on poetry and general literature at the Royal Institution, which were afterwards published in one volume. He was now recognised as a standard English classic, unrivalled in popular sacred poetry and in the poetry of the domestic affections by all but Cowper. His verse was clear, copious, and flowing; always musical, and often strikingly picturesque. If he had no secret beauties of diction or subtle trains of thought and imagination, his works displayed a high and pure moral feeling and strong religious faith, untinctured by sectarian formality or exclusiveness. In his

poetry, as in his life, James Montgomery exhibited a catholic spirit that embraced whatever was lovely and of good report. He looked beyond the grave, but never neglected any form of suffering humanity or call of active duty and brotherly sympathy.

In 1841 a collected edition of Montgomery's works was published in four volumes; and so late as 1853 he issued a series of *Original Hymns*. To his limited means—the small hoard accumulated through years of toil and anxiety—the government, on the recommendation of Sir Robert Peel, added a pension of L.150 per annum. The latter years of the old poet were thus passed in ease and comfort. To all benevolent and missionary schemes he lent a willing hand; his townsmen were proud of him, and his society was much courted. When he had nearly reached the allotted period of threescore and ten, he made a pilgrimage to Scotland, and finding out the house in the "Half-way" of Irvine where he first saw the light, he shed a flood of tears at the humble scene of his birth. He was publicly received by the magistrates and other inhabitants of Irvine; and in Edinburgh he also met with a marked and honourable reception. His history altogether affords a fine example of virtuous and successful perseverance, and of genius devoted to pure and noble ends,—not a feverish, tumultuous, and splendid career, like that of some greater poetical heirs of immortality, but a course ever brightening as it proceeded,—calm, useful, and happy. He attained to the great age of more than eighty-two years, dying at his residence near Sheffield on the 30th of April 1854. Memoirs of his life and writings, with extracts from his correspondence and journals (somewhat too voluminous and indiscriminate), have been published, in 7 vols. 8vo, 1855–6, by two of his friends, John Holland and James Everett. A complete edition of his poetical works appeared in 1855, in 4 vols. 12mo. (R. C—s.)

MONTGOMERY, Robert, the author of several religious poems, was born at Bath in 1807. He had hardly reached his twenty-first year when his poetical fame was established by the publication of his *Omnipresence of the Deity*. His swelling epithets, and the pompous roll of his versification, satisfied the majority of the readers of poetry; his choice of his theme recommended him to the religious public; and at the same time the dullness of his intellect, the barrenness of his imagination, and his many broken metaphors, passed undetected. The poem, therefore, reached an almost unprecedented popularity, and passed through eight editions in an equal number of months. Stimulated by this success, his versifying faculty produced in the same year another volume containing, *A Universal Prayer, Death, A Vision of Heaven, and A Vision of Hell*. *Satan* followed in 1829, and raised the author's reputation to its greatest height. Montgomery now began to contemplate studying for the church. He entered Lincoln College, Oxford, in 1830, took the degree of B.A. in 1833, and was ordained in 1835. His first pastoral charge was the curacy of Whittington in Shropshire. From it he removed in 1836 to Percy Street chapel, London. By this time his preaching was acquiring a popularity scarcely less false in its foundation than that which had greeted his poetry. The crowds that flocked to hear him mistook his affected attitudes for studied elegance, his vague generalizations for profound thinking, and his noisy ranting for true oratory. His fame as a preacher continued to increase after he had removed, in 1838, to his ultimate charge of St Jude's chapel, Glasgow. Towards the close of his life he published several works, both prose and poetical, on religious subjects. He died at Brighton in December 1855.

MONTGOMERY, a municipal and parliamentary borough of Wales, capital of the county of the same name, is placed at the foot of a high and well-wooded eminence, about 1½ mile from the Severn, and 168 N.W. by N. of

Montgomery.

Mont-
gomery
||
Mont-
gomery-
shire.

London. It is small but well built; and has four principal streets, meeting in a market-place in the centre. The principal buildings are,—the church, an old edifice in the form of a cross, with a modern tower; the guildhall; and the county jail. The borough returned a member to Parliament from the time of Henry III. till the passing of the Reform Act; but since that time it has formed one of six boroughs which together elect one representative. The ancient castle of Montgomery, of which some ruins still remain, was founded by Baldwin, a follower of William the Conqueror, who was appointed Lieutenant of the Marches by that monarch. In consequence of its situation on the borders of England and Wales, it was long considered an important stronghold; and was the subject of frequent contention between the Saxons and the Normans. It received its present name from Roger de Montgomery, Earl of Shrewsbury, by whom it was enlarged and strengthened. It afterwards passed into the hands of the crown, by whom the stewardship was granted, in the fifteenth century, to the Herberts of Cherbury. Pop. (1851) 1248.

MONTGOMERY, a town in the United States of North America, capital of the state of Alabama, is built on an eminence on the left bank of the Alabama River, 197 miles N.E. of Mobile, and 331 miles above it by river. The town contains 7 churches, 2 academies, a state-house, a bank, and 6 newspaper offices. In the neighbourhood of Montgomery is one of the richest cotton-producing districts of Alabama, and 75,000 bales are annually shipped here. The river is navigable for steamers as far as Montgomery; and as it is never impeded by ice, large vessels ply between this town and Mobile at all seasons of the year. The town is also connected by railway with Atlanta in Georgia; and another line is in progress towards the west. Montgomery has several very pleasant suburbs; and is a very prosperous and enterprising town. Pop. (1850) 4935; (1853) estimated at 7000.

MONTGOMERYSHIRE, an inland county of North Wales, having on the E. Shropshire, N. Denbighshire and Merionethshire, W. Cardiganshire and Merionethshire, and S. Radnorshire. It is of an irregular form, its greatest length from E. to W. being about 40 miles, and its greatest breadth from N. to S. 36 miles. Its area measures 755 square miles, and contains 385,290 statute acres. It is thus third in point of size of the Welsh counties.

This county, traversed as it is throughout its entire length by one of the largest of British rivers, the Severn, possesses scenery of the most varied and attractive character. It has few very lofty mountains; but the whole county is diversified with a succession of hill and dale and the most beautiful river scenery. Towards the English border there are extensive tracts of finely-cultivated land, and everywhere the surface is beautified by fine woods, chiefly of oak. The parks of Lord Powis, Lord Sudeley, and other large landed proprietors in this county, vie in beauty with any in the British Islands. The principal mountain range is that of Plymlimon, 2463 feet in height, which gives birth to the rivers Severn and Wye. The Dovey, the Tanat, and the Vyrnwy are the other principal streams. There are but few lakes of importance.

The climate is for the most part mild; and agriculture has made greater progress in this than almost any of the other divisions of the principality. Many of the farms are of large size, and are cultivated in a spirited manner. Mr Naylor's model farm at Leighton Hall, near Welshpool, is one of the most complete establishments of the kind the British Islands can boast of. The cultivated crops consist of wheat, barley, oats, buckwheat, and rye; vetches, peas, beans, clover, and clover-seed; mangold, carrots, turnips, and potatoes; flax and rape. There are also extensive orchards. Montgomeryshire has long been famous for its breed of hardy horses and ponies, for which high prices are

obtained. The cattle are chiefly of the Hereford breed, and the sheep the Shropshire Downs; but there is a breed of small sheep produced on the borders of this county known as "Cluns," which are highly prized. Monti.

The lead mines of this county are very important, and are now (1857) yielding largely. At Llangynog the famous Llangynog Mine, in the hands of Sir Hugh Middleton, yielded for a long period more ore than all the other mines in Britain, furnishing those immense resources which brought the New River to London, and which greatly contributed to the wealth of the then lords of Powis. The ore was quarried like stone in great open quarries. These mines afford the finest example of what is called a "gash" vein known in the world. The whole county rests upon the Upper and Lower Silurian group of rocks; but there are numerous outcrops of intercalated beds of trap, affording, when investigated by means of the mines, a curious and most interesting study to the geologist.

This county is connected with the Dee at Chester by the Chester and Ellesmere Canal. It has also lately completed a small railway from Newtown to Llanidloes, and has got acts for two others.

Besides Montgomery, the principal towns are,—Welshpool, Newtown, Llanidloes, Machynlleth, and Llanfyllin. Welshpool is the thriving, general business town of the county. Newtown and Llanidloes are chiefly devoted to the manufacture of Welsh flannels, of which they form the chief seat, and possess mills of great size, which are worked by the newest and most improved machinery. Montgomeryshire returns one member to Parliament, and has done so since 1536. It possessed 2986 registered electors in 1852; and the political influence is wholly in the hands of Sir W. Wynn and the Earl of Powis.

The population, by the last census, was 67,335, of which 33,634 were males, and 33,701 were females. The population was less in 1851 by 1300 persons than in 1841. In 1851 there were 13,350 inhabited houses, 716 uninhabited, and 25 building. These figures give 89 persons and 18 houses to a square mile, or 7.2 acres to each person and 36.2 acres to a house,—nearly the same proportions as Brecon possesses.

The amount of real property assessed for income-tax in 1851 was £340,192; amount of property rented to the poor, £280,833. It is computed that 15 per cent. of the population live by agriculture, and 10 per cent. by trade. About one-fourth are labourers, servants, &c.; 400 persons are in professions; and 1000 possess independent means.

The total number of churches in Montgomeryshire in 1851 was 346, with 62,886 sittings. Of the former, 66 belonged to the Church of England, 191 to the Methodists, 58 to the Independents, and 26 to the Baptists. According to the census of 1851, there were in Montgomeryshire 1272 day schools, with 6194 scholars (3857 males and 2957 females), of which 72 schools, with 4854 scholars, were public. Of the public schools, 3, with 136 scholars, were supported by general or local taxation; 18, with 1264 scholars, were supported by endowments; and 51 schools, with 3554 scholars, were supported by religious bodies. There were also 312 Sunday schools, with 23,001 scholars (11,612 males, and 11,389 females); and 6 evening schools, with 130 scholars. English is more spoken in this county than Welsh, owing probably to its manufacturing industry.

MONTI, VINCENZO, an eminent Italian poet, was born in the Romagna on the 19th of February 1754. He received his elementary education at the seminary of Faenza, where he acquired an extensive knowledge of the Latin language, and became passionately attached to the Roman poets. By his father he was destined to follow the profession of agriculture; but as he continued to evince a predilection for literature, the elder Monti sent the youthful poet to the university of Ferrara to study law or medicine. Young

Monti. Monti ultimately resigned himself wholly to the cultivation of literature and poetry. His first Italian poem was entitled, *The Prophecy of Jacob*; and although an unequal production, it contains some vigorous, and even sublime passages. About this time the perusal of Dante opened up to him new and splendid views of the grand old style of his native land, and henceforth the bard of the *Divina Commedia* became his model and his master. His admiration of Dante bordered on idolatry, and catching a portion of the inspiration of that great poet, he wrote the *Vision of Ezekiel*, in which he displayed that grandeur of imagery and fluent command of language which distinguish his compositions. Monti was at this time scarcely eighteen years of age. His genius attracted the notice of Cardinal Borghese, who conducted him to Rome. Here he extended his knowledge of the classics, and his acquaintance with the learned; but it was not until 1780 that public attention was directed to him. The compositions which he recited on the occasion of the celebration of the quinquennial of Pius VI. drew forth such general applause, that Don Luigi Braschi, the Pope's nephew, made him his private secretary. His next composition of any importance was his tragedy of *Aristodemo*, written, it is said, to rival the *Virginia* of Alfieri, which he had heard the poet read before a literary club. The very great success of his *Aristodemo* induced Monti to write another drama, entitled *Galeotto Manfredi*, which proved an entire failure. His genius was not dramatic, but lyrical; and highly-wrought imaginative rhapsodies were more in accordance with the natural bias of his mind, than the concatenation of plots and the delineation of human passion.

Monti being attached to the papal court when the revolutionary Basseville was stabbed in the streets of Rome, laid hold of this circumstance, and celebrated at once the repentance of Basseville and the decapitation of Louis XVI. in a poem entitled the *Basvilliana*. This production is entirely supernatural in its construction. The soul of the murdered man, like the body of Moses, is contended for by the angel of God and the enemy of mankind; and although the former is triumphant, yet the disembodied spirit of the republican is doomed for a certain period to hover about the banks of the Seine, and to witness all the atrocities which are there perpetrated. The subject is treated with great power, and the imagery with which the poem is adorned is in the highest degree original and majestic. As a whole, it approached more nearly to the grandeur and sublime daring of Dante than anything which had been produced for centuries; and the fame of Monti rose above all rivalry. But the tide of French republicanism having now set in upon Italy, entirely changed the aspect of affairs in that country, and brought Monti into close contact with some of Napoleon's generals. To this circumstance we must attribute the admiration which the poet began to entertain for the French hero, and the lively anticipations of good to be derived by his country from the new order of things which were awakened in his mind. The enthusiasm of Monti hurried him away with the general current in which so many ardent young hearts were borne along.

In a mythological poem entitled *Musogonia*, he paid court to Napoleon; and in a still finer production, *Prometeo*, he enthusiastically celebrates the triumphs of the Gallic chief, at the same time pouring out the vials of his wrath upon England. On the decay of the Napoleonic influence in Italy, Monti was compelled to seek refuge beyond the Alps, where he fell into a state of the most deplorable destitution. The return of Napoleon, however, and his new victories in Italy, afforded Monti an opportunity of partially retrieving his fortunes. He returned to Milan, and there published his poem, the *Mascheroniana*, the chief object of which is to bind new wreaths of victory

around the brow of Napoleon. Shortly afterwards, Monti produced a third tragedy, entitled *Caius Gracchus*; and in 1802, an ode, in which he calls upon his military idol to place himself at the head of the Italian people, which Bonaparte did not long hesitate to do. The rewards of the poet were, first, a professorship at Pavia, and, a few years subsequently, a number of offices and honours at Milan. In 1805, when Napoleon was crowned king of Italy, the event was celebrated by Monti in a poem called *Il Beneficio*. Indeed, every fresh victory and new conquest of the Emperor of France afforded a theme for the courtly muse of the Italian poet. The triumph of Jena resounded in his ode entitled the *Spada di Federico*; the attempted usurpation of the Spanish throne was sung in the *Palinogenesi*; and various other conquests were celebrated in numerous odes and hymns. Besides these works, he finished, in less than two years, a translation of the *Iliad*, which, without possessing much spirit, is considered elegant and faithful.

The overthrow of Napoleon in 1814 deprived Monti of all his public employments; and after this period, although he composed an occasional poem, his labours were chiefly confined to prose. The principal of these are, considerations on the difficulty of properly translating the poetry of the *Iliad*, and several dialogues on the Italian language, full of wit and acute criticism. By an order of government to reform the national dictionary, his attention was for a time engrossed with the subject of language. He undertook a crusade against the Della Cruscans, attacking their decisions with the utmost vigour and no common success. He continued to reside at Milan; and in 1823 he once more turned his thoughts to poetry. He restored the true reading of the *Convito* of Dante, wrote an idyl on the nuptials of Cadmus, and then contemplated the completion of the *Feroniade*, a poem which he had begun many years before. He had nearly accomplished his design when death put a final period to his labours on the 13th October 1828, in the seventy-fourth year of his age. (J.F.S.)

MONTIVILLIERS, a town of France, department of Seine-Inférieure, pleasantly situated at the head of the fertile valley of the Lézarde, 6 miles N.E. of Havre. Many of the houses are of wood, and have an antique and picturesque appearance; but the beauty of the town arises chiefly from the clear stream which flows through it, and the trees by which it is surrounded. The church, which is in the Romanesque style of architecture, formerly belonged to a Benedictine abbey of the seventh century. Manufactures of cotton and woollen stuffs, lace, paper, leather, and sugar are carried on here. There is also some trade in corn, cattle, groceries, &c. Pop. 4195.

MONTLUCON, a town of France, capital of an arrondissement of the same name, in the department of Allier, is situated near the Cher, here crossed by a stone bridge, 39 miles S.W. of Moulins. It is well built on the slope of a hill, the summit of which is crowned by the remains of a castle, formerly a place of much strength. Manufactures of linen, serge, candles, &c., are carried on; and there is some trade in cattle and agricultural produce. Pop. (1851) 8810.

MONTMORENCY, ANNE DE, constable of France, was descended from one of the most ancient French families, and was born at Chantilly in 1493. He was brought up along with the young Dauphin, afterwards Francis I., and on the accession of that prince he was raised to an influential position. He was not long in proving himself worthy of his good fortune. His chivalrous valour was conspicuous in several campaigns, and gained for him a marshal's baton in 1522, soon after the outbreak of the war against Charles V. Contrary to his advice, however, the battle of Pavia was fought in 1525, and he found himself in consequence a prisoner, along with his sovereign, in the hands of the Emperor. On being

rency.

Montmorency.

ransomed, he contributed in no small degree to effect the release of his royal master. But as Francis I. refused to fulfil the conditions of his liberation, Montmorency was in course of time called upon to defend France against Charles V. He continued by his skilful manœuvres to harass and repel the enemy till war was superseded by negotiation. As a reward for these services, the office of constable of France was conferred upon him in 1538. In this lofty position, the austerity of his morals and the roughness of his manners appeared in greater prominence, and excited against him much dislike at court. It is not surprising, therefore, that he was disgraced in 1541. He bore his exile with great magnanimity, until the accession of Henri II., in 1547, recalled him to his office of constable, and to greater influence than ever. His military talents were called into requisition in 1557, to relieve St Quentin from a besieging army of Spaniards. But a hazardous plan, which he had begun to execute, for the purpose of entering the city, failed, and left him wounded and a prisoner in the hands of the enemy. As an aggravation of this misfortune, he discovered, when he was released at the peace of 1559, that the Guises, during his absence, had been supplanting him in the favour of the King. The death of Henri II., and the accession of Francis II., in that same year, completed his disgrace. He returned to court, however, on the accession of Charles IX., and played an important part in the struggle which was then beginning to convulse France. His firm devotion to the Catholic religion induced him to make common cause with his former enemy, the Duke of Guise, against the Prince of Condé and the King of Navarre, the leaders of the Huguenots. In the civil war that followed in 1562, he gained the victory of Dreux over Condé, but was himself made a prisoner. On his release in the subsequent year, he expelled the English from Havre. In 1567 the civil struggle was renewed, and Montmorency once more encountered the Protestants on the plains of St Denis. His troops were already in the full pursuit of victory when he received a mortal wound. He died on the 12th of November 1567.

MONTMORENCY, *Henri II. Duc de*, grandson of the preceding, was born at Chantilly in 1595. His career began under the most favourable circumstances. He was the godson of Henri IV., and was constantly receiving marks of the royal affection. His illustrious name, his winning manners, his generous spirit, and his chivalrous valour, rendered him at an early age the darling of the court and the people. Hardly had he attained his eighteenth year when Louis XIII. raised him to the office of admiral. Yet his good fortune was not greater than his desert. He wrested several important places from the Protestants, and was present at the sieges of Montauban and Montpellier. On the renewal of the civil war in 1625, the fleet sent from Holland to the aid of the French King was placed under his command. Kindling the lukewarm Dutch soldiers by his fiery enthusiasm, he captured at their head the Isles of Rhé and Oleron. He then in 1628 measured his strength in Languedoc against the Duc de Rohan, and was not worsted in the contest with that famous leader of the Huguenots. His brightest laurels, however, were won during the following year in the war against the Spaniards in Piedmont. Falling in with an army under Doria at Veillane, he charged across a ditch at the head of the gendarmes of the King, struck down the hostile general with his own hand, and fought like a common soldier until the enemy was completely driven from the field. This brilliant victory was followed by the raising of the siege of Casal, and the appointment of Montmorency to the rank of Marshal of France. In the height of his fame and influence he was now solicited to join the opponents of Cardinal Richelieu. His pride, pampered by so many successes, was quick to incite him to hostility against

one who was so deadly a foe of the nobility; and he rushed into open rebellion with his characteristic impetuosity. In his character of governor of Languedoc, he raised levies of troops and money in 1632, and, after forming a junction with Gaston, Duke of Orleans, saw himself at the head of an army of six or seven thousand. Negotiation was tried in vain; and in September Montmorency was confronted at Castelnaudary by an army under La Force and Schomberg. At this crisis he forgot the caution of the general in the headlong valour of the soldier. Bursting into the royal camp at the head of a few horsemen, he cut his way through six ranks of infantry amidst a continued shower of shot, and fought against overwhelming numbers, until his horse dropped dead, and left him in the power of his enemies. He was doomed to death by the inexorable Richelieu, as an example to the rest of the plotting nobility. In vain was his life begged by all ranks throughout France. The only palliation of punishment that could be obtained from Louis XIII. was that the execution should be in private. Montmorency was therefore beheaded in the Hotel de Ville of Toulouse in October 1632.

MONTMORILLON, a town of France, capital of an arrondissement of the same name, in the department of Vienne, is situated on both sides of the Gartempe, 27 miles S.E. of Poitiers. It was formerly a strong place, and still contains the remains of an old castle, part of which is now used as an ecclesiastical college. The town possesses a few paper-mills and bleachfields, and it has some trade in cattle. Pop. 4400.

MONTOIR, a town of France, in the department of Loire-Inférieure, 11 miles W. of Savenay. The manufacture of vitriol is carried on here; and large quantities of peat are obtained in the neighbourhood. Pop. 4500.

MONTORO, a town of Spain, in the province of Cordova, is situated on a rocky eminence, nearly surrounded by the Guadalquivir, 27 miles N.E. of Cordova. It is closely built; but the streets, though narrow and steep, are well paved and lighted. The town has a market-place and four public squares; a parish church, with a Gothic front and a lofty tower; another church; a town-house; an hospital; and several educational institutions. There are quarries and mines in the neighbourhood, but these are not now worked. The town has several flour and oil mills; and the principal article of export is oil. Pop. 10,732.

MONTPELLIER, a town of Vermont, in the United States of North America, capital of the county of Washington, is situated on both sides of the Onion River, 200 miles N.W. of Boston, and 85 S.E. of Montreal. The principal edifice in the town is the State House, built of granite in the form of a cross, 150 feet in length by 100 in breadth, and surmounted by a dome 100 feet high. The portico in front has six pillars, each 6 feet in diameter and 36 in height. The cost of this magnificent building was about L.60,000. Montpellier has also a court-house, five churches, two banks, and five newspaper offices. The trade is considerable; and the town is connected by a branch with the great line of railway between the Atlantic and the St Lawrence. Pop. (1850) 2310.

MONTPELLIER, a town of France, capital of the department of Hérault, is situated on an eminence on the right bank of the Lez, 30 miles S.W. of Nîmes, and 17 N.W. of Cette, the port of this town. It is irregularly built, with narrow, steep, but generally clean streets; and the houses are mostly well built. The public places are for the most part small in size and irregular in form; and the public buildings are unworthy of so large a town. The latter consist chiefly of a cathedral, with no pretensions to beauty or interest; an exchange, with a fine Corinthian colonnade; a court-house; a medical school, &c. Of the fortifications with which the town was once surrounded there are now few remains, except the citadel and

Mont-
pellier.

some of the gates; the ancient ditches being now occupied by boulevards, which, along with the esplanade between the citadel and the town, and the Promenade de Peyrou, occupying the summit of the hill at the other end, serve as public walks for the recreation and amusement of the inhabitants. The last of these, which forms the chief attraction of the town, but is perhaps overpraised when it is regarded as one of the finest public walks in Europe, consists of shady avenues and neat parterres, adorned with fountains and pieces of sculpture. It is surrounded by balustrades, and has a fine Doric arch at its entrance, an equestrian statue of Louis XIV. in the centre, and a Corinthian building of hexagonal form, called the Chateau d'Eau, at its further extremity. This edifice forms the terminus of an aqueduct, about 5 miles in length, raised for the distance of 2896 feet upon a double tier of arches, which conveys water for the use of the town, and supplies the numerous fountains which adorn it in different places. Montpellier is distinguished for its school of medicine, which was founded in the twelfth century by the Arabs who were expelled from Spain. This institution, which now occupies the old episcopal palace, is celebrated as the place where Rabelais studied medicine and took the degree of doctor; and it now rivals in excellence and fame the medical school of Paris. It has large anatomical collections, and a library of 35,000 volumes and 600 MSS. The botanic garden of Montpellier, the earliest collection of the sort in France, was established in the reign of Henri IV.; and having been for some time under the superintendence of the celebrated De Candolle, who was professor of botany at Montpellier, it is now one of the best arranged in France. Montpellier has also several hospitals, which are both large and well managed. Among the other celebrities of the town must be noticed the collection of paintings contained in the Musée Fabre, an institution founded in 1825 by an artist of that name who was born here. It includes, besides the picture gallery, a library of 15,000 volumes, including those which once belonged to Alfieri. The manufactures of Montpellier are considerable, and some of them, such as that of verdigris, which is obtained by placing plates of copper between grape husks, are carried on in few other places. There are, among other establishments, cotton and woollen factories, dye-works, paper-mills, distilleries, breweries, sugar-houses, and chemical works for the making of alum, Prussian blue, &c. An active and extensive trade is carried on with the port of Cette, and with the neighbouring towns and villages. The principal articles of export, besides the produce of the manufactures, are wine, oil, fruits, wool, and other rural produce. Montpellier enjoys a great reputation, especially in the north, as having a very temperate and healthy climate, and is frequently recommended as a residence for invalids; but though the heat is not so intense nor the air so close as at Marseilles, yet the temperature is very changeable, from the scorching glare of sunshine to the cold breezes of the *mistral*. The advantages of this town seem to have been exaggerated, both in respect of the salubrity of its climate and of the beauty and retirement of its situation. Towards the end of the eighth century, when the neighbouring city of Maguelonne embraced the side of the Saracens, and was in consequence destroyed by Charles Martel, Montpellier, which seems to have been formerly a small village, was first raised into the position of an important town, governed by hereditary lords under the bishops of Maguelonne. In the two following centuries the lords of Montpellier were not a little distinguished in the Crusades and other wars with the Infidels; while the town is represented as vying as a place of trade with the chief cities of that age. In 1202 the lordship of Montpellier passed by inheritance to the family of Aragon, and afterwards to a younger branch of that family, who were also Kings of Majorca. It was purchased in 1350 by Philip

VOL. XV.

Montreal.

VI. of France from James III. of Majorca, for 200,000 crowns of gold. It was conferred by Charles V. on Charles of Navarre, in exchange for certain other lordships; but in 1578 the possessions of that monarch were confiscated for high treason, and Montpellier returned into the possession of France. The town still remained, however, distinct from the rest of France in its language and customs; and all the Kings of France, till the time of Louis XI., had to visit it in person in order to secure its allegiance. At the Reformation a great number of the inhabitants embraced the side of the Huguenots. In 1622 the town was attacked by Louis XIII., and after a siege of two months, surrendered; after which event the citadel was built to keep the town in subjection. Montpellier was the birthplace of Cambacérès and Cambon, who played an important part in the first French revolution; of the historian Daru; of the chemist Chaptal; and of several other distinguished characters. Pop. (1851) 40,222.

MONTREAL, a town of Lower Canada, capital of a cognominal county, and the largest city in British America, is situated on a triangular-shaped island of about 30 miles in length and 7 in breadth, at the confluence of the Rivers St Lawrence, and Ottawa, N. Lat. 45. 32. 22., and W. Long. 73. 32. 46. It was founded in 1642, and called Ville Marie, by a French company, which had for its object the conversion and civilization of the Indian tribes. During fifty years the settlers were harassed by the treacherous attacks of the Iroquois; but by a heroic resistance they at length succeeded in securing the tranquillity of the colony. On the 8th September 1760 Montreal was finally delivered up to the British, in whose hands it has since remained in peaceful possession. The town was then defended by some old fortifications, but these were demolished about the beginning of the present century, and replaced by wide and substantial streets. In 1815 the city scarcely contained 15,000 inhabitants; now its population is estimated at 75,000, and is steadily increasing.

The St Lawrence, on the left bank of which Montreal is situated, has a length of 742 miles above the city, and links together the celebrated combination of lakes which contain the largest amount of navigable fresh water on the surface of the globe; their total area being 98,000 square miles; while the extent of their coasts, if stretched out in a straight line, would measure upwards of 6000 miles.

The River Ottawa, which joins the St Lawrence both above and below the town, drains an area of about 80,000 square miles; and Montreal being the highest point to which the St Lawrence is navigable for sea-going vessels drawing 18 feet of water, it may be considered as the chief port of the great St Lawrence system.

The city is situated on the left bank of the St Lawrence, 300 miles from its mouth, and stands at the foot of an isolated hill, from which it takes its name. This eminence is composed of trap, which bursts through the Lower Silurian limestone of the vicinity, and rises to the height of 750 feet above the harbour. The slopes at its base are beautifully studded with orchards and villas, those on the side next the river gradually mingling with the buildings of the city.

The city occupies an area of 7 or 8 square miles. Its principal streets run parallel with the bank of the river; and all the public edifices, with a large proportion of the private dwellings, are built of cut limestone, derived from extensive quarries in the immediate neighbourhood. The majority of the houses, however, are of brick, roofed with tin, which from a distance produces a sparkling effect on the landscape.

The views from the mountain behind the city are very striking and beautiful. From the one side, looking to the upper end of the island, the eye takes in a fine expansion of the St Lawrence, called Lake St Louis, with a portion of the Lake of Two Mountains, backed by the

hills which give it name. A well-cultivated and wooded district stretches to the westward and north-westward, watered by the Ottawa, and bounded at a distance of about 30 miles by the Laurentian Hills.

On the east side of the mountain, on the other hand, the city occupies the foreground, adorned with the steeples of its numerous churches, and inclosed by the St Lawrence, which has here a breadth of from 1 to 2 miles. Above the city the bed of the river is occupied by Nun's and St Helen's Islands, the latter rising to a height of 150 feet. In the interval between these islets the great Victoria bridge is in course of erection, for the purpose of connecting Montreal Island with the mainland, and completing the links of the Grand Trunk Railroad. This stupendous bridge, which when finished in 1859 will be the largest in the world, is to be of the following dimensions:—Its total length will measure 10,384 feet; the span of each of the twenty-five arches will be 242 feet, with the exception of the centre one over the navigable channel, which will measure 330 feet. In this arch the height from the water-level of the river to the floor of the iron tube will be 60 feet. The limestone masonry, with rock-faced ashler work, will contain 2,900,000 cubic feet; the iron tube will weigh 10,400 tons; and the cost of the whole is to amount to L.1,250,000 sterling.

From the east side of the river, opposite Montreal, there extends a wide champaign country, the natural fertility of which is attested by the fact, that a large part of 1,000,000 bushels of wheat, exported from Lower Canada so early as the year 1801, was derived from it. This flat region is thickly studded with farm houses, and it is broken by a number of isolated trap mountains. Beyond these a prolongation of the Green Mountains of Vermont are visible, some of them attaining here a height of about 4000 feet above the St Lawrence. Some excellent roofing slates and beautiful white granite are found in the ridge, and are now partially used in the city.

At Montreal, and nearly all the way down to Lake St Peter, the channel of the St Lawrence is scooped out of a black bituminous shale; while 2 or 3 miles above the town this shale is cut by trap dykes, and becomes intercalated with trap beds. The river, changing its upward bearing from southward to westward, here crosses the stratification, and its wearing action having been resisted by the superior toughness of the trap and the solidity of the limestone, a natural dyke is formed, which keeps the Lake St Louis at a higher level by 44 feet than the harbour of Montreal, and gives origin to the Lachine or St Louis rapids. In these the whole body of the river, contracted to half a mile, rushes with a rapidity of 18 miles an hour; and although they are navigable downwards for steamers drawing 10 feet, they of course present an insuperable barrier to any ascent of the stream being attempted.

To obviate this and similar obstructions to the navigation, a magnificent system of canals has been established, called the St Lawrence Canals. These are nine in number, and 42 miles in length. Twenty-seven locks occur in the system, by which a rise of 205 feet is obtained, and which are capable of floating vessels of 200 feet in length by 45 feet in breadth, and drawing 9 feet of water. The lowest section, which avoids the Lachine rapids, commences at the port of Montreal, and, with a length of 9 miles, reaches Lake St Louis at Lachine, opposite Caughnawaga. The town, however, is otherwise benefited by the sudden fall of the river here, as great facility is thereby afforded for an ample supply of fresh water being conveyed into the city. By means of the new water-works the water is brought from the St Lawrence about $1\frac{1}{2}$ mile above the Lachine rapids, at an elevation of 37 feet above Montreal harbour, and conducted for 5 miles along an open canal, 43 feet wide by 8 in depth, to the

pumping machinery, where it is forced up to reservoirs excavated out of the solid rock 205 feet above the level of the harbour, and which contain about 15,000,000 gallons of water. Gas-light is also abundantly supplied by a company incorporated in 1847, who had laid down a length of pipe in 1855 of 34 miles. What most attracts the stranger, however, in Montreal is the number of its public buildings, which could well be compared with those of any town of similar size in the New World. Of these the greater number are for religious or charitable purposes. One of the largest Catholic churches was consumed in the great conflagration of the 8th July 1852, which destroyed one-third of the city. The English cathedral was also destroyed by fire in December 1856. Preparations are now made for the rebuilding of both churches on a much larger scale. The Catholic parish church, which was opened for public worship in 1829, is one of the finest sacred edifices in North America. It measures 241 feet in length by 135 feet in breadth, and is surmounted by two lofty towers, which rise to the height of 213 feet. The cost of the whole building amounted to L.80,000. A chime of bells belonging to this church is much admired, particularly the great bell, which weighs 25,000 lb., and was cast in London twelve years ago by Mears. Besides these there are other Catholic churches—that of St James', erected on the ground of the ancient cathedral of Notre-Dame; Bonsecours and Recollet for the French Canadians; and St Patrick's and St Ann's for the Irish, who form one-third of the Catholic population. Of the Protestant churches the most remarkable are St George's, St Andrew's (a fine Gothic edifice), the Wesleyan church in Great St James' Street, Zion church, and St Thomas's. These, with the new Unitarian and other places of worship, among which is the Jews' synagogue, impart an elegance to the architecture of the city. Among the charitable institutions there are the Hotel Dieu, whose origin dates as far back as that of the colony itself; and St Patrick's Hospital, a branch of the same, both of which are attended by the nuns of St Joseph de la Flèche, who receive and assist the sick. The General Hospital, founded in 1747 by Madame d'Youville, is attended by the Gray Nuns, who receive foundlings, orphans, and infirm persons; and who also have lately opened two other asylums in the interior of the city. The House of Providence is also open for aged and infirm persons. The English General Hospital, maintained by the liberality of government, and erected in a salubrious situation, is a very fine edifice, open to Catholics as well as Protestants, and to which deceased merchants of the city have left large sums of money. The Protestant Orphan Asylum, the Protestant Industrial House of Refuge, the University Lying-in Hospital, the Seamen's Friend Society, with many others, have rendered the greatest service to the community, and are well supported by the people. Of literary and educational institutions, there are few cities in North America which afford such easy and abundant means of education as Montreal. Without mentioning a number of private schools, there is M'Gill College, founded by the Hon. James M'Gill, a merchant in Montreal, who died in 1813, bequeathing to the institution, which was to bear his name, L.10,000, and the estate of Burnside, of 46 acres, within the city. Litigation, however, having ensued as to the validity of the bequest, which was left in trust to the "Royal Institution for the Advancement of Learning," it was settled in 1835 by a decision of the Privy Council. The bequest of L.10,000 amounted then to L.22,000, of which L.15,000 were expended on buildings. In 1852 Her Majesty, by a new charter, appointed the members of the "Royal Institution of Learning" governors of this university *ex officio*; and in 1856 a sum of about L.15,000 was subscribed by the citizens of Montreal for its advancement and extension,

Montreal. of which L.5000 were given by the Messrs Molson for the support of the "Molson Professorship of History and English Literature." The university is now in a flourishing condition, and has a principal, 5 professors of law, 9 of medicine, and 9 of arts, besides a high-school department, with a rector and 9 assistant-masters. The number of students was, in 1856, of law, 16; medicine, 96; arts, 54; and high school, 225; while the total number of volumes contained in the library amounted to 4036. The Montreal college, founded by the priests of St Sulpice a hundred years ago, and St Mungo's college, established a few years since by the Jesuits, number each about 200 students. There are also two normal schools, established in 1857. The M'Gill normal school is under the direction of the corporation of the university of M'Gill college. It is designed for the Protestant population of Lower Canada, and the instruction given is principally in the English language, although French is also taught. The Jacques Cartier normal school is also situated in Montreal, and is designed for the Roman Catholics of the surrounding districts. The instruction given is principally in the French language, but English is also taught. On the ground formerly occupied by the Mountain Fort, and commanding one of the most enchanting views in Canada, is erected a new theological Catholic seminary, an edifice of considerable dimensions. Besides these, there are the Canadian Institute for the French Canadians; the Mechanic's Institution, a building in the Italian style; and the Mercantile Library Association, the latter principally composed of young men acting as clerks in mercantile establishments. It is furnished with a library consisting of above 8000 volumes; and lectures on various subjects are delivered in its hall during the winter months. The national societies, so specially illustrative of colonial life, are likewise worthy of mention. They consist of the associations of St Andrew, St George, St Jean Baptiste, St Patrick, and New England, and have for their object the relief of such of their members as may become reduced in circumstances.

The only public monument in the city is one erected to Lord Nelson. It is situated in the market-place, is 60 feet in height, and is surmounted by a colossal statue of the hero. The Montreal Merchants' Exchange, the new post-office, and the several banks are all elegant buildings, and of various styles of architecture. The markets are well supplied with commodities; the largest of them are the Bonsecour's and the St Ann's. The town supports seven daily newspapers printed in English, and one daily in French; two French and one English semi-weekly paper; and three English weekly; besides sixteen other periodicals, published monthly and quarterly, on theological, medical, and literary subjects.

The commerce of Montreal, although it has from time to time received severe checks, has, in the aggregate, rapidly increased; and when the advantages of its position are considered, the ultimate importance of this city appears certain and immediate. As late as 1847 all Canadian produce was protected in the British markets. But in that year the differential duties were repealed, and the St Lawrence, which up to that time enjoyed a monopoly of Canadian trade, had to enter into competition with the United States; and the Drawback or Bonding Bill having at the same time come into operation there, the people of Western Canada were enabled to import foreign goods, or send their own produce through the United States in bond. On account of this change of commercial policy, and without the advantages arising from a repeal of the Navigation Laws, as now in force, the trade of Montreal suffered severely. The imports and exports, which in 1846 amounted to L.2,845,008, declined in 1849 to L.2,013,478; but in 1856 the value of imports and exports at the port amounted to L.4,992,565. A rivalry now exists between the state of

New York on the one hand and East Canada on the other, as to which shall be successful in attracting the trade of Upper Canada and the Western States of the Union, to New York on the Atlantic, or to Montreal on the St Lawrence. The merchants of this port are well aware of the measures necessary to command success. The shoals which obstructed Lake St Peter and other parts of the river between Quebec and Montreal have been removed, and the depth of water increased throughout from 11 feet to 18 feet at the lowest water; while it is expected that in 1859 the channel from Montreal to the sea will be brought to a depth of 20 feet at the lowest water, and a width of 300 feet. The magnitude of this work can be estimated by the fact that, when completed, 5,074,491 cubic yards of silt will have been removed. Sailing vessels of 2000 tons, and steamers of 3000 tons, will then be able to enter the port of Montreal from the sea. New docks are also projected for the accommodation of such vessels; and with storehouses connected therewith, such facilities will be obtained for the ocean and western vessels exchanging their cargoes as cannot be excelled at any other port in North America. Montreal is 300 miles nearer Liverpool than the port of New York, and is nearer also to any port in Upper Canada, or in the Western States, than that city. At present, however, the shipping of Montreal is exceeded by that of Quebec, and many vessels from the former port are re-cleared at the latter, and *vice versa*. In 1854 an aggregate seaward tonnage of 72,305 entered Montreal, against 59,712 in the preceding year; and an aggregate seaward tonnage of 73,917 cleared from the port in 1854, against 59,902 in 1853.

By railway Montreal is connected with all the most important points. The Grand Trunk Railroad extends from St Thomas (80 miles below Quebec), and from Portland (Maine) to Montreal, and from thence to Stratford, having a total mileage of 850 miles. The Champlain Railroad extends from St Lambert, opposite Montreal, to Rouse's Point, in Lake Champlain, a distance of 45 miles. The Montreal and New York Railroad, including distance by ferry, extends from Montreal to the Province line, a distance of 39 miles; and these railroads, with the Great Western Railroad from Niagara Falls and Hamilton to Windsor on the Detroit River, place Montreal in communication with Quebec, Portland, and all ports of the United States. In addition to these advantages, Montreal is the terminus of the Canadian line of ocean steamships, now running every fortnight between Montreal and Liverpool, and also under contract to run in 1859 every week during the period of navigation, and once every fortnight during winter, to Portland. Lines of telegraph are in connection with all parts of Canada and of the United States; while a bill has been obtained by the Montreal Telegraph Company to carry a wire down the St Lawrence, to connect at Newfoundland with the projected cable across the Atlantic. Another work which must result greatly to the benefit of Montreal, is the construction of a ship canal from the St Lawrence, near the town, into Lake Champlain. The distance is about 28 miles. This would tend more than any other public work to give important advantages to the St Lawrence route.

Montreal is also the seat of a large manufacturing interest, and from the immense water-power, in the fall of 44 feet of the St Lawrence within a distance of 7 miles, it is evident that manufactures within and near the city must rapidly extend. At present the only water-power is furnished from the Lachine Canal, and here several thousand men are employed in cotton and woollen mills, edge-tool factories, boiler and engine works, saw-mills, sash, blind, and door factories, Indian-rubber, rope and cordage, nail, axe, and shovel factories. The manufacture of boots and shoes is likewise carried on to a large extent.

The value of assessed property in 1856 was L.6,391,333

Montreal.

Montrose. and the revenue of the town from all sources L.71,258. The city is divided into nine wards, and is municipally governed by a mayor, aldermen, and council, elected by householders who pay an annual rent of ten pounds sterling or upwards, or persons who own real estate producing half that amount of rent annually. The city returns three members to the provincial Parliament. Pop. (1851) 57,715, and in 1857 about 75,000. (J. Y.)

MONTROSE, a royal and parliamentary burgh and seaport-town of Scotland, Forfarshire, 30 miles N.E. of Dundee; 56. 42. N. Lat., and 2. 28. W. Long. It is situated on the west side of a narrow sandy peninsula formed by the German Ocean on the E., the South Esk River on the S., and on the W. by a large basin not less than 7 miles in circumference, into which the tide, flowing up the South Esk, spreads itself after passing the town. This "basin" becomes dry at low-water; but its alternate filling and emptying as the tide ebbs and flows has an important effect in scouring and deepening the harbour. On the east side of the town, and between it and the sea, are extensive links or downs, belonging to the community of the burgh, and forming one of the finest golfing-grounds in Scotland. The town is in general well built, is lighted with gas, and amply supplied with excellent water, brought from the valley of the North Esk, 3 miles distant. The principal street extends, under various names, the whole length of the town; and the centre part of it, named the High Street, is spacious, and contains many elegant buildings. An excellent statue of Sir Robert Peel is one of the finest ornaments of this street, and another of Mr Hume is about to be erected. From the east side of this main street run several cross streets, which connect it with the different smaller streets and buildings lying in that direction. The town-house, which stands in the High Street, is a handsome edifice of three storeys, with an arcade below, and contains the council-room, guild-hall, court-room, news-room, and public library. Besides this, Montrose contains numerous public buildings, among which are two churches belonging to the Establishment, two to the Free Church, two to the United Presbyterian, and one each to the Independent, Methodist, and Scottish Episcopalian denominations. A chapel belonging to the English Episcopalians, burnt down in 1857, is shortly to be replaced by a commodious place of worship. The Baptists and Glassites have each a small place of worship. The old lunatic asylum in the Links, erected in 1780, is about to be sold, and a new one is in course of erection 2 miles from the town, at a cost of about L.25,000, and with accommodation for 400 patients. A spacious infirmary was erected in 1837; and in 1833 a commodious jail, adjoining which a police-office has since been built. Dorward's House of Refuge for the Destitute, built in 1839, and endowed by Mr William Dorward, affords accommodation for about 200 paupers. The Academy, a fine edifice, erected 1814, has a rector, an English teacher, 2 assistant teachers, a writing and a drawing master. Dorward's seminary, originally erected by the seven incorporated trades in 1832, but subsequently endowed by William Dorward, is now under the charge of his trustees. Besides these, there are two endowed free schools—White's, having 100 boys; and Miss Straton's, with 42 boys and 35 girls. There are also an infant and several private and denominational schools. There are two subscription libraries, the one having about 10,800 volumes, the other, supported chiefly by the working-classes, 3000 volumes. A newspaper was established in 1811, named the *Montrose, Arbroath, and Brechin Review*, which is published every Friday morning; and another in 1837, also published on Friday, called the *Montrose Standard*. A branch railway to Dubton, two miles distant, connects the town with the Scottish N.E. Railroad. The great northern turnpike crosses the South Esk by means of two bridges; one of stone, with a revolving

drawbridge in the centre, on the S. side of the small island of Inchbrayock; the other a magnificent suspension-bridge, from Inchbrayock to the N. side of the river. It was designed by Captain Brown, the patentee of chain cables, and finished at a cost of about L.20,000. The foundation-stone was laid on the 18th of September 1828. The distance between the towers at the two extremities of the bridge, measuring from the centre of each, is 432 feet. There are four main chains, supported by two strong towers, 71 feet in height, and these form the grand entrance to the bridge on each side, through an archway 16 feet wide by 18 feet high. A pontage is levied at the bridge. In 1838 a large portion of the roadway of this bridge was blown down; after which it was much strengthened and improved. The harbour is formed by the outlet of the River South Esk, the channel up to the quays being 172 yards in width by 15 feet in depth at neap tides. A wet dock was constructed in 1839, $3\frac{1}{4}$ acres in extent, with 19 $\frac{1}{2}$ feet of water in spring, and 16 in neap tides, over the sill. There are two good lighthouses between the harbour and the sea, and a patent slip for repairing vessels. The harbour-dues for year ending May 1857 amounted to L.4301. On 31st December 1856 there were 96 vessels, of 15,292 tons, registered at the port; and during that year 753 vessels entered the harbour; while in 1857 the number had risen to 925. The tonnage of these two years was respectively 60,515 and 75,503. In 1857 the principal imports were,—flax, 5551 tons; coals, 44,566 tons; timber, 17,668 loads; herrings, 7412 brls.; guano, 1682 tons; wheat, 9876 qrs. The chief exports were,—wheat, 7036 qrs.; barley, 7862 qrs.; oats, 1607 qrs.; timber, 7394 loads; potatoes, 39,677 bolls.

The chief manufacture is flax-spinning, carried on in 5 mills, employing about 2000 hands, and consuming nearly 5000 tons of flax annually. The number of small hand-loom has greatly diminished of late years. Instead of 600 in 1848, there are now only about 250. But, on the other hand, there are now about 160 power-loom employed on the Forfarshire fabrics, besides 80 broad looms on floor-cloth and wide linen sheetings of fine quality. Ship-building has for many years been actively carried on. There are four building-yards. Two saw-mills have recently been erected, driven by steam-engines of 80 horse-power, and giving employment to about 100 men. The other factories comprise three foundries, two machine manufactories, two breweries, two large rope and sail works, and two artificial-manure works, with bone-mills, a starch-work, four herring and fish-curing works employing 40 boats and 250 fishermen and others, two candle-works, and a large cabinet and upholstery manufactory.

The burgh of Montrose received its first charter from David I. about the beginning of the twelfth century; but, from the tenor of that charter, it seems to have been a burgh even before that time. Sir James Douglas embarked from this port in 1330 for the Holy Land, with the heart of King Robert Bruce. Montrose is distinguished as the first place in Scotland where the Greek language was taught, and as having sent forth from its seminary the learned scholar and divine Andrew Melville. The celebrated Marquis of Montrose was born here. In 1716 James the Chevalier embarked here for France, after his unsuccessful attempt to raise the country; while in later years (1777) it became the birthplace of Joseph Hume, the distinguished financial reformer.

The annual revenue of the burgh corporation amounts to nearly L.3000; while the estimated value of the property of the same, after deducting debts, was, in 1857, L.38,509. Montrose is governed by 19 councillors, including a provost, 3 bailies, dean of guild, treasurer, and master of the foundation called the Ancient Hospital. It unites with Arbroath, Forfar, Brechin, and Bervie, in returning a member to Parliament. Pop. of parliamentary burgh (1841), 15,094; (1851),

Montrose.

Montserrat. 15,238; of royal burgh (1851), 14,328. The constituency is 432.

Montserrat.
||
Montucla.

MONTSERRAT, one of the smallest of the British West India Islands, belonging to the Leeward group, and about equally distant (30 miles) from Antigua, Guadeloupe, and Nevis; N. Lat. 16. 40., and W. Long. 62. 10. It is of an oval form, mountainous on its eastern shores, and has a gradual slope westward to the sea. Area 30,720 acres. The island is of volcanic origin, and characterized by great abruptness, both in the elevation of its hills and in the descent of the valleys. Vegetation is everywhere abundant, and reaches in trees and shrubs to the greatest heights of the island, viz., about 2500 feet. The climate is remarkably salubrious. The chief productions are the sugar-cane, arrow-root, and timber. Owing to the heavy taxation on land, however, the full resources of its soil have not yet been developed, although of late years much has been done in lightening those burdens; and thus, in all probability, the planters here will shortly be able to compete with those on the other islands, or on the mainland. There being no other class or trade on the island than that of landholders, the legislature has been obliged to lay the entire taxation on them; and consequently in 1855 we find that 33 per cent. was taxed on the letting value of a farm for the purposes of government, besides about 25 per cent. more on the imports, which include here many of the necessities of life. This system, however, is being gradually ameliorated in its effects by the rigid economy of the government. The trade of Montserrat is carried on exclusively with the neighbouring islands. In 1855 the imports amounted in value to L.7704; and in 1854 to L.8963; while the exports of the former year amounted to L.19,986, against L.14,515 in 1854. The chief imports are corn, cottons, dried fish and preserved meats, manure, and hardware; the principal exports, sugar (L.13,552 worth in 1855), molasses, and rum. In regard to the shipping, there was in 1854 a tonnage of 4562, against 3986 in the preceding year, entered; and a tonnage of 4589 in 1854, against 4310 in 1853, cleared from the island. The government of Montserrat is administered (under the governor-in-chief of the Leeward group) by a president and an executive council of eight members appointed by the crown, who also form the legislative council. There is, besides, a representative assembly, consisting of 12 members. In 1855 the revenue amounted to L.3500, and the expenditure to L.3264. Education, which has been productive of much good here, was dispensed in 1854 in 18 schools, attended by 1623 scholars, of whom 891 were females. This island was discovered by Columbus in 1493, and named after a mountain near Barcelona. In 1632 a party of Irish Roman Catholics from St Christopher's settled on it; and after experiencing a French invasion in 1712, the island was finally made over to Britain by the treaty of Breda in 1783. Representative government was first established here in 1689. Plymouth, the capital, is situated on the S.W. of the island. Pop. of island (1851) 7053, the great majority of whom are blacks.

MONTUCLA, JEAN-ETIENNE, a learned mathematician, was the son of a merchant, and was born at Lyons in 1725. He attended the college of the Jesuits in his native city, and was early distinguished by his tenacious memory and his aptitude for mathematics. At the age of sixteen he removed to Toulouse to prosecute the study of law; and after taking the usual degrees he repaired to Paris. There his conversational powers, his solid information, and his acquirements as a linguist, soon introduced him to the notice of the learned. In the society of D'Alembert and Lalande, his taste for mathematical studies was confirmed and stimulated. After publishing two anonymous treatises on the *Quadrature of the Circle*, and the *Duplication of the Cube*, he gave to the world in 1758 the first part of his great work, *The History of Mathematics*. Not long after this

his merits were recognised by the French government, and he was promoted to several important offices. He was appointed intendant-secretary at Grenoble in 1758, secretary to the expedition for colonizing Cayenne in 1764, and *premier commis des bâtimens*, and censor-royal for mathematical books, in 1765. During the next twenty-five years his time was divided between his official duties and the study of his favourite science. The Revolution then ensuing, deprived him of his income, and left him in great destitution. The offer in 1795 of a mathematical chair in one of the schools of Paris was declined on account of his infirm health, and he was still in straitened circumstances in 1798, when he published a second edition of the first part of his *History*. He also enlarged Ozanam's *Mathematical Recreations*, afterwards published in English by Dr Hutton, 4 vols., Lond. 1803. About four months before his death a pension of 2400 francs was conferred upon him. He died in December 1799. His *History of Mathematics* was completed by Lalande, and published in 4 vols. 4to, 1799-1802.

MOODKEE, a small town of Hindustan, 25 miles from the left bank of the River Sutlej, 1140 miles N.W. from Calcutta; Lat. 30. 48., Long. 74. 55. It is only remarkable for a victory gained by the British over a greatly more numerous force of the Sikhs on 18th December 1845. This was the first action in that war, and the loss of the English was very considerable, more than fifty European officers being killed and wounded.

MOOLTAN, or **MOULTAN**, a province of Hindustan, constituting one of the territorial divisions of the Punjab, and containing an area of 15,494 square miles, with a population amounting to 971,175.

MOOLTAN, the capital of the above province, situated 4 miles from the left bank of the Chinaub or Acesines, below the points where it receives the waters of the Ravey (*Hydraotes*) and the Jhylum (*Hydrastes*), and about 30 miles above its confluence with the Indus. It was formerly inclosed by a fine wall from 40 to 50 feet in height, with towers at regular distances; and had a citadel on a rising ground. The vicinity is covered with an amazing quantity of ruins of tombs, mosques, and shrines, which show the former extent and antiquity of the city. The adjacent country is fertile, well cultivated, well watered from wells, and productive of wheat, millet, cotton, turnips, carrots, and indigo. Mooltan is noted for the manufacture of silks, and for a species of carpet, which, however, is much inferior to those of the Persian manufacture. This is supposed to have been the city known anciently by the name of Malli; and in 1582 it is described by Abul Fazel as one of the most ancient cities of Hindustan. It was plundered by Mahmoud of Ghizni about the year 1006, and was again plundered by Timour in 1398. For many years the nawaub paid a tribute annually, for protection, to the sovereign of Cabul. In 1806 it was captured and plundered by Runjeet Singh. In 1809 the nabob was obliged to pay tribute to the Ameers of Sind; and in 1818 it was again captured by Runjeet Singh, who cut to pieces the garrison of 3000, with the exception of a small number admitted to quarter. Subsequently to the death of Runjeet Singh, and during the distracted times which ensued, this place again furnished an object of contention. In 1848 the atrocious conduct of Dewan Moolraj, who held the fortress where two British officers were basely assassinated, called for the renewal of hostilities on the part of the British, which were rendered memorable by the energy and enterprise displayed by Major Herbert Edwardes, then only a subaltern. At that time the citadel of Mooltan was represented as being more regular in construction than any other stronghold laid down in India by native engineers. The wall was surrounded by thirty towers, and protected by a ditch faced with masonry. On the 2d January 1849 the city was

Moodkee
||
Mooltan.

Moon
||
Moor.

captured by a British force under General Whish, after an obstinate and gallant defence; and on the 22d, practicable breaches having been effected, the British troops were about to storm the citadel, when Moolraj with his whole garrison surrendered unconditionally. A few months later the destruction of the fort was completed by the elements, when the most violent storm ever remembered occasioned the flooding of the rivers of the Punjab. It was not thought advisable to repair the fortress. An obelisk, erected in the town by order of the British government, preserves the memory of those who fell in the Sutlej and Punjab campaigns. The circumstances under which this part of Runjeet Singh's territories became a portion of the British dominions will be found detailed in the article PUNJAB. The population of Mooltan, including the suburbs and cantonment, is given at about 80,000. Lat. 30. 12., Long. 71. 30.

MOON. See ASTRONOMY, part ii., chap. iii., &c.

MOOR, a market-town of Lower Hungary, in the province of Thither Danube, and county of Stuhlweissenburg, is situated in a valley 17 miles N.W. of Stuhlweissenburg. It contains a strong castle, large cavalry barracks, two churches, a monastery, a town-hall, and many well-built houses. There are several brandy distilleries here, and a considerable trade in corn, horses, and cattle. Pop. about 7000.

MOOR, JAMES, an eminent Greek scholar, was born at Glasgow on the 22d of June 1712. His father, James Moor, was a teacher of mathematics in that city, and was distinguished for great devotion to scientific and literary pursuits. Young Moor entered the university of his native city in November 1725, and soon attained to great proficiency in classical literature and mathematical science. In Greek he enjoyed the instructions of Alexander Dunlop, who combined with a thorough knowledge of the language a remarkable power of inspiring his students with a love for the study. The celebrated professor of mathematics, Dr Robert Simson, alludes repeatedly throughout his writings to the eminent talents of Moor for mathematical pursuits. After completing his academical course, he opened a school for classics and mathematics, but not succeeding in this undertaking, he speedily relinquished it. He now became a private tutor, and was connected successively in that capacity with the families of the Earl of Kilmarnock and the Earl of Selkirk. On the 11th November 1742 he was appointed librarian to the university of Glasgow; and during the same year, in conjunction with Dr Hutcheson, published an anonymous translation of *The Meditations of the Emperor Marcus Aurelius Antoninus*. On the resignation of the Greek chair by Dunlop in 1746, Moor was unanimously elected to the vacant professorship. He still continued to combine the study of classical literature with the study of the mathematical sciences; and during his residence in Paris in 1748, he received assistance from the eminent Greek scholar Capperonnier in researches on which he was then engaged connected with an edition of the Greek text of Pappus. This undertaking, which was never completed, was superseded by the more magnificent one of a complete and splendid edition of the works of Plato. This project originated with the Messrs Foulis of Glasgow, who, after being at great labour and expense in collecting materials for the undertaking, were compelled to relinquish a scheme which Dr Moor, the editor, and many other distinguished scholars throughout the kingdom, had very much at heart. The entire collection for this edition of Plato is now in the possession of the Bodleian Library at Oxford. The earliest fragment of Moor's *Grammar of the Greek Language* appeared in 1755; and after an interval of fifteen years, the work appeared with its final improvements, under the title of *Elementa Linguae Græcæ; novis plerumque Regulis tradita, brevitate sua memoriæ facilibus, &c.*,

Glasgow, 1770, 8vo. A short time after the first appearance of his *Grammar*, he published (1759) a small volume of *Essays on the influence of philosophy upon the fine arts, on the composition of the picture described in the Dialogue of Cebes, and on historical composition*. His next work was his *Spartan Lessons, or the Praise of Valour in the Verses of Tyrtæus, &c.*, which appeared anonymously in 1759. In 1763 he published an essay on that passage of Aristotle's *Poetics*, in which we are told that tragedy purifies the passions by means of pity and terror. Moor did not seem to understand how this was possible, and he accordingly questioned the ordinary interpretation of the author's language. His endeavour, however, to discover a new translation of the passage, was more ingenious than successful. The next production of his pen was an acute tract *On the Prepositions of the Greek Language, an Introductory Essay*, Glasgow, 1766. It was characterized by great ingenuity; but the soundness of his theory of the Greek prepositions has been called in question by several distinguished scholars. During the same year he published his *Vindication of Virgil from the charge of a puerility imputed to him by Dr Pearce, in his Notes on Longinus*. In addition to his original works, Moor is known to have assisted in editing various editions of those Greek classics which issued from the press of the Messrs Foulis. He edited the *Arenarius* of Archimedes; the works of Herodotus, 9 vols., 1761; the works of Thucydides, 8 vols., 1759; and, conjointly with Muirhead, the professor of humanity in Glasgow, edited the splendid copy of Homer, in 4 vols., which issued from the university press in 1756-58. As a relaxation of his severer studies, the professor is said to have indulged occasionally in the composition of English and even of Scotch verses. Some of these poetical effusions appeared in various publications of the time; but he does not seem to have been endowed with much genius for song. In 1761 he was appointed vice-rector of his university; and the senatus conferred upon him the degree of LL.D. in 1763. His health had been giving way for some time, and he was constrained to resign his professorship in 1774. He was allowed to retain his house and salary, but his domestic affairs got into disorder, and he was relieved from the annoyances of pecuniary embarrassments only by death on the 17th September 1779.

MOORE, EDWARD, a dramatist of the last century, was the son of a dissenting minister, and was born at Abingdon in Berkshire in 1712. He followed the business of a linen-draper for some time in London, but was forced by ill fortune to become a literary adventurer. His first poetical work, entitled *Fables for the Female Sex* (1744), imitated with success the pungency and flowing versification of Gay. It speedily became popular, and secured for its author the patronage of several men of influence. A favour shown him by Lord Lyttelton was the occasion of his next work, a complimentary effusion, styled *The Trial of Selim the Persian*. Moore then turned his attention to the drama. His two comedies, *The Foundling* (1748), and *Gil Blas* (1749), were unsuccessful. But his rare power of riveting the attention by a tale of domestic sorrow secured for his tragedy *The Gamester* a footing on the stage, which it still retains. It was published in 1753, and has been often reprinted. Hitherto the labours of Moore had not been sufficiently remunerative. He was therefore installed as editor of *The World*, a periodical which had been established by his friend Lyttelton, for the purpose of affording him a sure income. In this office he continued until the serial was brought to a close in February 1757. By this time sixty-one papers had been contributed by his own hand. He died while the last number of his periodical was passing through the press. A quarto edition of his *Poems, Fables, and Plays* was published in 1756, and a separate issue of his *Dramatic Works* appeared in 1788.

Moore,
Edward.

Moore,
Dr John
||
Moore,
Sir John.

MOORE, DR JOHN, was the son of a clergyman, and was born at Stirling in the year 1730. He received his medical education at the university of Glasgow, and at the age of seventeen he served with the army in Flanders. After the conclusion of peace, he prosecuted his medical studies at Paris, where he was appointed surgeon to the household of the English ambassador, Lord Albemarle. On his return to Scotland he settled as a surgeon at Glasgow, where he quickly rose to extensive and successful practice.

In the year 1769 he was called, in his medical capacity, to attend the young Duke of Hamilton, which led to his subsequently accompanying the brother of his patient to the Continent. An extensive and long-continued tour through Italy, France, and Germany, opened a wider range to his observation of character than he had hitherto enjoyed. After spending five years abroad, he settled as a physician in London; and about the same time commenced his literary career by publishing the fruits of his travels in his *View of Society and Manners in France, Switzerland, and Germany*, 2 vols., Lond. 1779. This work was so well received, that in 1781 he added to it two volumes, entitled *A View of Society and Manners in Italy*. In 1785 he published his *Medical Sketches*, consisting chiefly of observations on the animal economy and the treatment of fevers. His next performance, which appeared in the year 1789, was a novel entitled *Zeluco*, in which he has exhibited a character so atrocious as rather to excite horror than afford amusement or instruction. It was much admired, however, on its first appearance, and was hailed as a work of very great power.

In 1792 Dr Moore accompanied Lord Lauderdale to Paris, where he witnessed some of the principal scenes of the Revolution, of which he published an interesting account on his return to England, entitled *A Journal of a Residence in France during the Revolution 1792-4*. The same journey supplied him with materials for his *View of the Causes and Progress of the French Revolution*, which was published in 1795. The scenes which Dr Moore had hitherto exhibited, both in his travels and fictitious compositions, were copied from the manners of other countries. The novel of *Edward*, which he published in 1796, is entirely confined to the illustration of our domestic usages and national customs. *Mordaunt, or Sketches of Life, Character, and Manners in Various Countries*, possesses something of the same sort of merit as *Edward*, but in an inferior degree. He survived the publication of *Mordaunt* only two years, and died at London in 1802. In addition to the works already signalized, Dr Moore published an edition of Smollett's works in 8 vols., with a Life of the author, Lond. 1797.

The reputation of Dr Moore with posterity will rest on his travels and novels. As long as they are read, he will be acknowledged as a writer endowed with admirable good sense, a rich vein of original humour, keen insight into human nature, and a capacity of describing its intricacies with force and discernment.

A complete edition of his works, in 7 vols., with a Memoir of his life, was published by Dr Robert Anderson, Edinburgh, 1820.

MOORE, Sir John, a consummate British general, a brave soldier, and an accomplished gentleman, was born at Glasgow on the 13th of November 1761. He was a son of Dr Moore, the author of *Zeluco* and other works, noticed in the preceding article, and received the principal part of his education on the Continent, whilst his father attended the Duke of Hamilton in his travels. In 1776 the Duke of Hamilton procured him an ensigncy in the 51st regiment, then quartered in Minorca; and he afterwards obtained a lieutenancy in the 82d, with which he served in America until 1783, when he was reduced with his regiment. By the interest of his former patron he was subsequently brought into Parliament for the Lanark district of

burghs, which he for a short time represented. In 1787 or 1788 he obtained the rank of major in the fourth battalion of the 60th regiment, then quartered at Chatham, but afterwards negotiated an exchange into the 51st. In 1790 he succeeded by purchase to the lieutenant-colonelcy of the same regiment, which, the following year, he accompanied to Gibraltar. After some other movements, he was sent to Corsica, where, owing to a misunderstanding between the military and naval commanders, General d'Aubant resigned the command to him under the most critical circumstances; and here, though still a young officer, and without parliamentary friends, he was called to fight the battles of the army against a domineering old admiral, Hood, who possessed great influence at home, and who had shown himself capable of the most outrageous violence. By dint of firmness, however, he succeeded in controlling this daring, obstinate, clever man; and was at length relieved from the difficult and embarrassing situation in which he had been placed by the arrival of Sir Charles Stuart, who having assumed the command of the army in 1794, appointed Moore to command the reserve. At the siege of Calvi which followed, the latter particularly distinguished himself, and received his first wound in storming the Mozzello fort. He gave his opinion against besieging Bastia, which afterwards surrendered after a very feeble defence, though the place was strong and the garrison numerous; but this, as a military judgment before the event, was nevertheless sound and just, for Moore never could have anticipated that General Gentili would neglect to avail himself of the means in his power, "because he wished to do his duty and no more," and had property in England.

Sir Charles Stuart having been recalled in consequence of a disagreement with the viceroy, Colonel Moore returned to England in 1795, and being immediately appointed a brigadier-general in the West Indies, he was attached to a brigade of foreign troops, consisting of Choiseul's hussars, and two corps of emigrants. On the 25th of February 1796 he received orders to take charge of and embark with Perryn's brigade, destined to join the expedition to the West Indies under Sir Ralph Abercromby. Having hurried to Portsmouth, where he had scarcely time to prepare a few necessities, he sailed for the West Indies on the 28th, with no other baggage than a small portmanteau. He arrived at Barbadoes on the 13th of April 1796, and there waited on the commander-in-chief, who had preceded him in the Vengeance line-of-battle ship. That calm and sagacious observer soon appreciated his merit; and in the operations against St Lucia, which immediately followed, employed him in every arduous and difficult service. During the siege of Morne Fortunée, his conduct, as expressed in general orders, was the admiration of the whole army; and after the capitulation he was appointed to the government of the island, notwithstanding he had earnestly requested permission to accompany the commander-in-chief and the troops in the reduction of the other islands. In this situation, beset with all manner of difficulties, his conduct was not less admirable than in the field, and, tempering justice with humanity, the severity of military examples with a due consideration of the circumstances which palliated the conduct of the Negroes and republicans, he subdued discontent, restored order, and re-established security.

Having completely re-established tranquillity in St Lucia, Moore was relieved from the command of the island, and returned to England in August 1797. In November, Sir Ralph Abercromby having received the command of the forces in Ireland, desired that General Moore should be placed on his staff, and the latter accordingly accompanied him to Dublin in the beginning of December. During the period immediately preceding the rebellion he held an important command in the south of Ireland, which, being much disaffected, was considered as the quarter where the enemy were, in the

Moore,
Sir John.

Moore,
Sir John.

event of an invasion, likely to attempt a landing. His headquarters were at Bandon, and the troops under his command, amounting to 3000 men, formed the advanced guard of the south. When the insurrection broke out in 1798, he was at first employed under Major-General Johnstone at New Ross, but was afterwards detached towards Wexford, at that time in the hands of the insurgents. On this occasion he had only the 60th sharpshooters, 500 light infantry, 50 of Hompesch's dragoons, and 6 pieces of artillery; and with these troops he had not proceeded above a mile when a large body of insurgents appeared on the road advancing to attack him. The rebels, amounting to about 6000 men, headed by one Roche, attacked with great spirit, and maintained the conflict with much obstinacy, but were at length defeated, driven from the field, and pursued with great loss. After the action he was joined by two regiments from Duncannon, and took post for the night upon the ground where the combat had commenced. Next day, when he had resumed his march, he was met by two men from Wexford with proposals on the part of the insurgents to lay down their arms and submit on certain conditions; but General Moore, having no power to treat, declined entertaining these proposals, and continued his march to Wexford, which he delivered from the power of the insurgents. He was afterwards employed to suppress a remnant of the rebellion in Wicklow, where many of the insurgents had taken refuge amongst the mountains and bogs, whence they issued to wage a sort of desultory warfare. Speaking of this affair in his journal, he says, that moderate treatment by the generals, and the preventing of the troops from pillaging and molesting the people, would soon restore tranquillity; that the latter would certainly be quiet if the gentlemen and yeomen would only behave with tolerable decency, and not seek to gratify their ill-humour and revenge upon the poor; and he adds, that he judged their harshness and violence had originally driven the farmers and peasants to revolt, and that they were as ready as ever to renew their former ill-usage of them.

These and other similar observations on the insurrection of 1798, extracted and published from General Moore's journal, do equal honour to his head and heart, evincing the discriminating and unimpassioned sagacity of the statesman, united with that high and liberal feeling which forms the greatest ornament in the character of the accomplished soldier.

Immediately after quitting Ireland, General Moore engaged in the memorable expedition to Holland. The Dutch, whom we sought to rescue from the alleged tyranny of the French government, made common cause with the enemy. They received the French as friends and deliverers, because the House of Orange, aided by Prussia, had destroyed their republic, suppressing their constitution and liberties; and hence, after a short struggle, the Duke of York was obliged to capitulate. But the troops displayed their usual gallantry, particularly those under the command of General Moore, who, after being wounded in the hand and thigh, received a musket-ball in the face, and was with difficulty brought from the ground. Being carried back to his quarters, a distance of 10 miles, he was taken thence to the Helder as soon as he could be moved, and embarked on board the *Amethyst* frigate, which arrived at the Nore on the 24th of August. Soon after his return to England the King conferred on him the command of a second battalion which had just been added to the 52d regiment; and his wounds having closed in the course of five or six weeks, he joined his brigade at Chelmsford on the 24th of December.

Early in 1800 it had been resolved to send a body of troops to the Mediterranean under the command of Sir Charles Stuart, and General Moore willingly consented to serve under that officer, whom he greatly esteemed. The

Moore,
Sir John.

first intention was, that the expedition should consist of 15,000 men; but it afterwards turned out that the regiments destined for the service, part of which had lately been employed in Holland, mustered only 10,000 effective soldiers. About the middle of March the first division, amounting to 5000 men, embarked under General Pigott. But at this time a change took place in the plan, if not in the destination, of the expedition. Sir Charles Stuart, having some misunderstanding with ministers, resigned his command; and Sir Ralph Abercromby being appointed to succeed him, named as one of his major-generals, Moore, who, along with Pigott and Hutchinson, sailed about the end of April with the second division of the troops. During this expedition, which a variety of causes conspired to render abortive, General Moore had little opportunity of signalizing his exertions; nor was it until the following year, when his troops were ordered to proceed to Egypt under Sir Ralph Abercromby, that a theatre of action opened for the display of his talents. On his arrival at Malta he was sent forward to Jaffa to inspect the Turkish army, and judge as to the amount of co-operation which might be expected from it; but his report being unfavourable, Sir Ralph determined to land in the Bay of Aboukir, and to march immediately upon Alexandria. In the affair of the landing on the 4th of March 1801, in the combat of the 13th, and again in the battle of the 21st, where he received a wound in the leg, General Moore was actively engaged, and as usual, greatly distinguished himself. On recovering from his wound, which occasioned him much suffering, he continued to serve with the army in Egypt until the surrender of Alexandria, when he returned to England, where he received the honour of knighthood and the Order of the Bath.

Soon after his return to England, we find Sir John Moore actively occupied in the camp at Shorncliff, where his skill in training troops was proved to be equal to his courage in leading them. Many persons have been led to suppose that he was a harsh and odious disciplinarian; but this calumny has been refuted by the most irrefragable proof. "The officers of the regiments which were formed by his care," says Sir William Napier (*Edinburgh Review*, vol. lix.), "were ever after his warmest admirers. His discipline it has been their object to maintain; his maxims have been their guide; his reputation has been by them considered as a part of their own; his memory is cherished in their hearts to this day, and will be as long as those hearts retain an atom of a soldier's pride and honour." Such is the testimony of one who knew him thoroughly; and who, besides his pre-eminent qualifications for judging rightly, had the best opportunities of understanding his views and appreciating his real character.

On the renewal of the war after the short peace of Amiens, Sir John Moore's talents and services pointed him out as deserving of some important employment. He was accordingly sent to Sicily as second in command to Sir John Stuart; and when that officer had been superseded by General Fox, he virtually acquired the chief command in that island. Associated with such a nominal superior, Moore had full scope for the exercise of his ability and sagacity; and indeed his whole proceedings showed that his sense and judgment in civil matters were in no degree inferior to his talents in war.

When Sir John Moore arrived in England from Sicily, he was immediately sent with an expedition to Gottenburg, to aid Gustavus Adolphus IV., King of Sweden, against the encroachments of Napoleon. While engaged on this expedition, he became involved in a grave dispute with the unreasonable Swedish king; and had it not been for the ability and resolution which he displayed on that occasion, 10,000 of the finest soldiers of England would have been sacrificed.

Moore,
Sir John.

We come now to the expedition to Spain, which terminated Sir John Moore's earthly career. In 1808 he was appointed to the chief command of an army to be employed in Spain; and Galicia, or the borders of Leon, were fixed upon as the place for assembling the troops. He was ordered to send the cavalry by land, but it was left to his own discretion to transport the infantry and artillery either by sea or land; and being at the same time informed that 15,000 men were ordered to Coruña under General Sir David Baird, he was directed to give such instructions to that officer as should facilitate the junction of the whole force. Before he commenced his advance from Portugal, he was assured that his entry into Spain would be covered by from 60,000 or 70,000 men; and Burgos was the place fixed on for the junction of the different divisions. But he soon discovered that these assurances were fallacious, that little or no reliance could be placed upon the Spaniards, and that the patriotic enthusiasm which he had been taught to expect in the people had either never existed at all, or had entirely evaporated. Not only Burgos, but Valladolid, was in possession of the enemy; and he found himself, with an advance corps, in an open town, at the distance of only three marches from the French army, without even a Spanish piquet to cover his front. At this time he had only three brigades of infantry, without a single gun in Salamanca; and although the remainder were coming up in succession, the whole could not be assembled in less than ten days. At this critical moment the Spanish armies, instead of concentrating or uniting in a common effort with the British, were disseminated all over the Peninsula; Blake had been defeated, and his army totally dispersed; Romana, equally weak and obstinate, proved incapable of undertaking anything; and Sir David Baird, informed that the French were advancing upon him in two directions, was preparing to retreat upon Coruña, a movement which was countermanded by Sir John Moore, upon learning that the report was unfounded. (See Sir William Napier's *History of the Peninsular War*, vol. i.) Never was a general commanding an army placed in a more critical position than Sir John Moore; for, whilst he received information that there was now no army remaining in the field except his own, which was thus exposed to attack on all sides by overwhelming numbers, he was called upon to repel the most irritating interference, to guard against open treachery, and to counteract folly, equal in its effects to treachery. Yet, even in these circumstances, he was willing to attempt something for the cause, and even to risk the danger of an advance on the capital. With this view he commenced a forward movement from Salamanca on the 12th of December, intending to attack Soult on the Carrion, draw the mass of the French force towards the north of Spain, and thus afford the Spanish armies time to rally and adopt some new plan of operations. This movement, in a strategical point of view, was ably conceived, and it proved to be well-timed and successful; but Sir John Moore, with 23,000 men, could not maintain himself against the whole French army; and as Napoleon, having secured the capital, was now rapidly advancing at the head of from 60,000 to 70,000 men, a retreat became inevitable. It was now the depth of winter, and the retreat had to be effected through the mountainous region of Galicia, which necessarily led to much suffering and disorder. There were not wanting many who blamed this retreat for precipitancy, but this charge has long since been shown by the best authorities to be unfounded. (See Napier's *History*, vol. i.)

The rear-guard quitted Astorga on the 1st January; on the 3d it repulsed the enemy in a sharp skirmish at Cal-cabelos; on the 6th it rejoined the main body at Lugo, having three times checked the pursuers during the march. It suffered no misfortune; and the whole army offered battle at Lugo for two successive days without being accepted. The

retreat recommenced; the troops reached Betanzos on the morning of the 10th, and Coruña on the 11th; and five days afterwards fought and won that celebrated battle in which their brave commander fell.

After the fight the British troops embarked and steered home directly from Coruña; a terrible storm scattered it; many ships were wrecked, and the remainder, driving up the Channel, were glad to put into any port. The soldiers, thus thrown on shore, were spread from the Land's End to Dover. Their haggard appearance, ragged clothing, and dirty accoutrements, things common enough in war, struck a people only used to the daintiness of parade with surprise; the usual exaggerations of men just escaped from perils and distresses were increased by the uncertainty in which all were as to the fate of their comrades; a deadly fever, the result of anxiety, and of the sudden change from fatigue to the confinement of a ship, filled the hospitals at every port with officers and soldiers; and thus the miserable state of Sir John Moore's army became the topic of every letter, and a theme for every country newspaper along the coast. The nation, at that time unused to great operations, forgot that war is not a harmless game, and judging of the loss positively instead of comparatively, was thus disposed to believe the calumnies of interested men, who were eager to cast a shade over one of the brightest characters that ever adorned the country. Those calumnies triumphed for a moment; but Moore's last appeal to his country for justice will be successful. And if authority be sought for in a case where reason speaks so plainly, future historians will not fail to remark, that the man whose talents called forth the praises of Soult, of Wellington, and of Napoleon, could be no ordinary soldier.

"Sir John Moore," says Soult, "took every advantage that the country afforded to oppose an active and vigorous resistance, and he finished by dying in a combat that must do credit to his memory." Napoleon more than once affirmed, that if Moore committed a few trifling errors, they were to be attributed to his peculiar situation, for that his talents and firmness alone had saved the English army from destruction. "In Sir John Moore's campaign," said the Duke of Wellington, "I can see but one error; when he advanced to Sahagun he should have considered it as a movement of retreat, and sent officers to the rear to mark and prepare the halting-places for every brigade; but this opinion I have formed after long experience of war, and especially of the peculiarities of a Spanish war, which must have been seen to be understood; finally, it is an opinion formed after the event."

The fall of Sir John Moore is thus described by Captain (now Sir Henry) Hardinge:—"I had been ordered by the commander-in-chief to desire a battalion of the Guards to advance, which battalion was at one time intended to have dislodged a corps of the enemy from a house and garden on the opposite side of the valley; and I was pointing out to the general the situation of the battalion, and our horses were touching, at the moment that a cannon-shot from the enemy's battery carried away his left shoulder and part of the collar-bone, leaving the arm hanging by the flesh. The violence of the stroke threw him off his horse on his back. Not a muscle of his face altered, nor did a sigh betray the least sensation of pain. I dismounted, and, taking his hand, he pressed mine forcibly, casting his eyes anxiously towards the 42d regiment, which was hotly engaged; and his countenance expressed satisfaction when I informed him that the regiment was advancing. Assisted by a soldier of the 42d, he was removed a few yards behind the shelter of a wall. Colonel Graham of Balgowan (Lord Lyndoch) and Captain (now Sir John) Woodford about this time came up, and perceiving the state of Sir John's wound, instantly rode off for a surgeon. The blood flowed fast, but the attempt to stop it with my

Moore,
Sir John.

Moore,
Thomas.

sash was useless, from the size of the wound. Sir John assented to being removed in a blanket to the rear. In raising him for that purpose, his sword, hanging on the wounded side, touched his arm, and became entangled between his legs. I perceived the inconvenience, and was in the act of unbuckling it from his waist, when he said, in his usual tone and manner, and in a very distinct voice, 'It is as well as it is; I had rather it should go out of the field with me.' When the surgeons arrived, he said to them, 'You can be of no service to me; go to the soldiers, to whom you may be useful.' As he was carried slowly along in the blanket, he made the soldiers by whom he was borne frequently turn him round to view the field of battle, and listen to the firing, and he seemed pleased when the sound grew fainter. On arriving at his lodgings he suffered great pain, and could speak but little; at length, however, he said to Colonel Anderson, who for more than twenty years had been his friend and companion in arms, 'Anderson, you know that I always wished to die in this way.' He frequently asked, 'Are the French beaten?' and when he was told that they had been defeated at every point, he said, 'It is a great satisfaction for me to know that we have beaten the French;' adding, I hope the people of England will be satisfied; I hope my country will do me justice.' To Major Stanhope he said, 'Stanhope, remember me to your sister;' and having mentioned the name of his venerable mother, for whom he seemed anxious to offer up his last prayers, he lost all power of utterance, and in a few minutes afterwards expired without a struggle."

Thus fell, on the 16th of January 1809, in the forty-seventh year of his age, after gaining a victory which saved the remainder of the army from destruction, and which, in all its circumstances, was perhaps unparalleled in the annals of war, Lieutenant-General Sir John Moore, a perfect model of a British soldier at a time when such models were few, and a hero cast in the true classical mould. He was equally a stranger to fear and reproach, yet one whom the malignity of faction basely attempted to deprive of his just fame, whilst venal pens endeavoured to depreciate his achievements, and servile poets vainly sought to exclude his name from the list of the brave who had fought and fallen in the same struggle. But his country was well disposed to acknowledge his merits, and history has already placed his character and actions beyond the reach of contemporary injustice.

(J. B.—E.)

MOORE, *Thomas*, one of the most accomplished and versatile authors of the nineteenth century, and pre-eminently the poet of Ireland, was a native of Dublin, in which city his father carried on business as a small grocer and spirit-dealer. He was born on the 28th of May 1779. His parents were of genuine Celtic-Irish descent, Roman Catholics, devoted to poetry and music, and possessing the quick sensibilities and warm domestic affections common among their countrymen. The poet's mother (to whom he was fondly attached) seems to have been a woman of great vivacity and spirit; and she joined with his first schoolmaster, Samuel Whyte (who had been the teacher of Richard Brinsley Sheridan), in cultivating in her son a taste for recitation, music, and theatrical performances, in which he early became distinguished. He was made a "show-child," as he confesses; and in a certain sense this character continued with him to the last, the scene being shifted from the gay social circles and private theatres of Dublin to the saloons of Holland House, Bowood, and other patrician mansions of the English aristocracy. Almost from infancy Moore had been accustomed to act, sing, and rhyme; and in his fourteenth year he appeared as a contributor to a Dublin magazine. His juvenile verses he afterwards characterized as "mere mock-birds' song," which is true of nearly all boyish rhymes; but in the department

of versification the Irish poet, guided by an exquisite ear, was from the first correct and harmonious.

Moore,
Thomas.

In 1793 the penal laws against the Roman Catholics were relaxed, and Moore was enabled to enter Trinity College as a student of his native university. The country was then agitated by political excitement, the offspring of the French revolution, acting upon a keen sense of national wrongs and humiliation. The poet sympathized with his oppressed Roman Catholic countrymen, and was intimate with Emmet and the other young and ardent spirits who rushed into the memorable conspiracy and outbreak of 1798; but he joined in none of their secret unions or wild revolutionary schemes. He completed his college course and took his degree of B.A. in 1798, after which he proceeded to London. Of the small sum of money which he carried with him, part, he says, was in guineas, carefully sewed in the waistband of his pantaloons by his mother, and along with the gold she had inclosed a *scapular*, or bit of cloth blessed by the priest! The good woman's prayers no doubt accompanied this treasure, and were more potent than the charm. In repairing to London, Moore had two objects in view—first, to study law in the Middle Temple, and then, as subsidiary to this professional purpose, to publish a translation of the Odes of Anacreon by subscription. With the law he made little progress; but his subscription was highly successful. He obtained an introduction to the Earl of Moira; the Earl introduced him to the Prince of Wales; and the poet's winning address, his scholarship, singing, and genial buoyancy of spirits, soon made him a favourite in fashionable and influential circles. His *Anacreon* appeared in 1800, dedicated by permission to the Prince. All who had listened to the "warbling" of the young translator, and who took an interest in his fortunes, were loud in praise of the work; while by critics and scholars it was considered as at least better than any preceding version of the Greek poet, with the exception of the few inimitable paraphrases by Cowley. "*Anacreon Moore*," as he was now called, ventured next year on a volume of original verse, which he put forth under the title of *The Poetical Works of the late Thomas Little, Esq.* The name of "Little" was a thin disguise, thrown off after the first edition, and originally adopted in playful allusion to the poet's diminutive stature; for Moore, as Walter Scott observed, was the smallest of men, not to be deformed. He was, as Goldsmith said of Garrick, "an abridgment of all that is pleasant in man." The poems were amatory productions, elaborately polished, and remarkably melodious in style and diction; but the chief distinction and peculiarity of the volume was its Ovidian warmth and pruriency, bordering on libertinism, which exposed its author to just and severe censure. Part was afterwards omitted from the collected edition of his works. Moore was not studiously immoral—his fancy played the profligate, not his heart; and one of his Irish friends, with a touch of native humour, compared him to "an infant sporting on the bosom of Venus." Through the influence of Lord Moira the poet obtained a government appointment—that of registrar to the Admiralty in Bermuda, which he took possession of in October 1804. The little islands, so delicious in climate, fruits, flowers, and foliage, appeared to him all fairyland; and his arrival was the signal for a succession of fêtes and gaieties. But when business was forced on his attention, it soon became obvious that the new appointment was no lucrative prize, and that even a Spanish war would not make his income worth staying for. Three months of Bermuda sufficed; a deputy was engaged, and the poet returned to England, travelling over part of the United States and North America, during which he visited, with a poet's enthusiasm, the Falls of Niagara. He reached London, after fourteen months' absence, in November 1804. The result of his journey was a volume of *Odes and Epistles*,

Moore,
Thomas.

published in 1806, and dedicated to Lord Moira. The work was well fitted to extend the poet's reputation. The Epistles contain many passages of beautiful and striking description, and are animated by a glow of generous sentiment, and a display of refined scholarly taste and subtle imagination peculiar to Moore among all the poets of his age. Some of the lyrical pieces in the volume—as the "Canadian Boat Song" and "The Woodpecker"—were set to music and instantly became popular. The work, however, was attacked with great asperity in the *Edinburgh Review*. Moore had indulged in severe strictures on the republican institutions and society of America, and some of the poems were tinged with that licentious freedom characteristic of the "Little" volume. Jeffrey branded the poet as a deliberate corrupter of the public morals. Moore replied by sending a challenge, and a hostile but bloodless meeting took place (August 12, 1806), which furnished a topic for nine days' wonder and ridicule, and proved the commencement of an acquaintance and life-long friendship between poet and critic.

About this time a musical publisher, Mr Power, projected a collection of the best original Irish melodies, with characteristic symphonies and accompaniments, and with words containing as frequently as possible allusions to Irish manners and history. Moore entered cordially into this patriotic undertaking, which ultimately became an important work, both as respected his fame and emoluments, and was extended to ten numbers. He knew the difficulty of the task. "The poet," he said, "who would follow the various sentiments which the airs express must feel and understand that rapid fluctuation of spirits, that unaccountable mixture of gloom and levity, which composes the character of his countrymen, and has deeply tinged their music." All this he felt and appreciated, and amply fulfilled. Burns alone has excelled Moore as a song-writer. If a third were added to form a lyrical trio, Béranger might be named; and all were intensely national, familiar with every shade of sentiment, prejudice, and feeling, in their countrymen. Moore has said that the real source of his poetic talent was the effort to translate into words the different feelings and passions which melody seemed to him to express; and his genius, thus inspired, ranged over all the fields of Irish song and story,—now swelling into heroic and martial verse, now revelling in joyous festivity, love, and wine, and now melting in strains of mournful regret, tenderness, and pathos. The union of poetry and music, their natural affinity and blended power, was never more felicitously exemplified than in these lyrics of Moore—the most universally popular, and, it may safely be predicted, the most imperishable of all his works. To the *Irish Melodies* were afterwards added *National Airs*, *Sacred Songs*, *Legendary Ballads*, *Evenings in Greece*, a *Set of Glees* (with music, also by the poet), and a number of separate songs and ballads. The lyric department of his poetry was at once the most voluminous and the most popular, and was constantly receiving additions.

For some years Moore was partially dependent on Lord Moira, and resided at his lordship's seat of Donnington Park. In 1811, however, he ventured on a step which gave a new turn to his feelings and prospects; he married a young Irish actress, Miss Dyke, the faithful "Bessy" of his *Journal*, who appears to have been every way worthy of his affection. Literature was now necessary as a profession; and in order that he might prosecute it with less interruption, Moore fixed his residence in an English village. He had an idea that the Irish neither fight nor write well on their own soil, and he seems never to have contemplated returning permanently to Ireland. He went to Kegworth in Leicestershire, but in the same year removed to Mayfield Cottage, near Ashbourne, in the county of Derby; and this spot may claim the honour due to scenes of poetical interest and vene-

Moore,
Thomas.

ration, for there Moore composed the best of his Melodies, and the greatest of his poems, *Lalla Rookh*. There was still a lingering hope that Lord Moira might be able to obtain some favourable appointment for the poet. His lordship was not indisposed to exert his influence, but his power was small; and in 1812 the removal of this nobleman to India put an end to Moore's expectations. He was averse to any application being made in his behalf to the ministry, and was resolved, he said, to work out his independence by industry. He had a justifiable reliance on the facility and versatility of his pen, and only wanted prudence to be one of the richest, as he was one of the best rewarded, of modern authors.

In 1813 Moore produced a political satire, *Intercepted Letters, or the Twopenny Post-Bag*, a series of light yet pungent rhyming epistles, suggested, perhaps, by Anstey's *New Bath Guide*, and which hit the public taste so well that thirteen editions were called for in a twelvemonth. The new and successful vein thus laid open was well cultivated in after years. Moore had previously tried the stately or Juvenalian style of satire; and in the years 1808 and 1809 produced three poems, *Corruption*, *Intolerance*, and *The Sceptic*, but they were heavy productions, and excited no attention. The lighter form of weapon to which he now betook himself was not only, he said, more easy to wield, but more sure to reach its mark. Up to the close of his poetical career Moore continued to throw off political squibs or satires on the topics of the day, and they are unsurpassed in our whole literature for wit, ingenuity, and brilliancy. They were published in the columns of the *Morning Chronicle* and *Times*, and seem to have brought their author an income of L.400 or L.500 a year. His imagination, he said, was the sole or chief prompter of this satire. It was possible, he conceived, to shower ridicule on a political adversary without allowing a single feeling of real bitterness to mix itself with the operation. Without a lively and fertile imagination such things could not indeed have been written; but Moore was a partisan as well as a poet; he felt keenly on all questions affecting his Irish Roman Catholic brethren, he was in daily association with the Whig leaders, and he had, besides, the natural antipathy of wit and genius to official dulness and pretence. But perhaps the main cause why a poet so little prone to bitterness should have so often and so long persisted in the use of this "flying artillery" of party warfare, was the unexampled popularity of his satires, and the large sums of money he obtained for them. When a few hours' occasional labour, that partook as much of amusement as of task-work, produced a cheque for a hundred pounds, and elicited immediate congratulation and applause, little else was required to stimulate the imagination. Moore was a man of quick rather than of strong or deep feeling; to such indignation or hatred as that of Swift he was a stranger. The political wrongs and injustice that lacerated the soul of Swift only awakened the poetical fancy and exercised the lively satirical ingenuity and wit of Moore.

The circumstances attending the publication of *Lalla Rookh* form an interesting chapter in literary history. In December 1814 the Messrs Longman, publishers, stipulated to give Moore the sum of L.3000 for a poem of the same length as Scott's *Rokeby*. They had seen no part of the work, and had to encounter, of course, the risk of failure; but they placed implicit trust in the genius and honour of Moore, and in the almost unbounded popularity of his name. After more than two years' delay the transaction was completed by the publication, in May 1817, of this eastern romance; and it is gratifying to be able to add that the enterprising and confiding publishers were fully compensated for their liberality and boldness, the poem having in the first year gone through seven editions. It possessed, indeed, all the elements of instant and decided success. *Lalla Rookh*

Moore,
Thomas.

abounds in picturesque and highly-wrought delineations of Eastern scenery and manners. It has the interest and attraction of four romantic tales, happily linked together by a small golden thread of narrative; it has a profusion of similes and sparkling imagery, and in some of the characters and incidents there are pictures of the loftiest heroism and the tenderest love. The versification is varied, spirited, and harmonious. The poet moves in the fetters of rhyme, whether in the heroic measure of Dryden or in the octo-syllabic verse of Scott, with the ease and grace of Ariel himself; and Ariel could not have desired a greater command of voluptuous sweets—of bowers of roses and nightingales, crystal fountains and fragrant groves, made radiant by the Houris of the East. The subject justified a large amount of this ornamental splendour and sensuous beauty; and the poet drew his materials from diligent study of oriental histories and books of travel. All is correct in external embellishment, costume, and decoration. The defect of the poem is its very riches. There is too much glitter and perfume; too many startling contrasts of loveliness and deformity, of rapture and agony; too visible a presence of art and preparation. The reader is lost in admiration, but gets fatigued as in a picture-gallery or hot-house, and sighs for the fresh breeze and simple aspects of nature.

While enjoying this new accession of fame and of release from the responsibility of an anxious engagement, Moore accepted an offer from Mr Rogers to accompany him to Paris. They spent a month in the French capital, and it furnished matter for Moore's next work, *The Fudge Family in Paris*, a satire which, he says, "prospered amazingly—five editions in less than a fortnight, and his share of the profits for that time L.350." The Marquis of Lansdowne had long wished the poet to take up his abode somewhere in his neighbourhood, and Moore removed to Sloperton Cottage, near Devizes, which was within an easy walking distance of Bowood. His settlement in this neat and modest poetical mansion (a thatched cottage, with garden, rented at L.40 a-year) was followed by what seemed at first to be a serious and almost irremediable misfortune. His deputy at Bermuda proved faithless, having not only kept back part of the receipts of the office, but appropriated to his own use the proceeds of a sale of ship and cargo, deposited in his hands by some American merchants. The poet was involved, it was feared, to the extent of L.6000; and a suit was instituted against him in the Admiralty Court. Attempts were made at a compromise with the crown and the American creditors; and while these were pending, the poet, ever sanguine and light-hearted, resumed his literary labours and social festivities. His next poem was a "flash satire," entitled *Tom Crib's Memorial to Congress*, published in March 1819. In July the Bermuda cause was finally decided in court, and an attachment was issued against Moore's person. One friend advised him to seek an asylum for a short time in Ireland, another recommended a retreat to the sanctuary at Holyrood, and a third counselled him to fly to France. All offers of pecuniary assistance from his friends he steadily declined. He went to France; and shortly after his arrival in Paris (Sept. 1819) he went with Lord John Russell on a journey to Italy. They travelled together as far as Milan, the poet having by the way "shuddered and shed tears" over the mighty panorama of the Alps, which he saw in all its sunset glory. Lord John took the route to Genoa; and Moore proceeded alone on a visit to Lord Byron at his villa near Venice. He subsequently extended his tour to Rome, and was fortunate enough to fall in with two eminent English artists, Chantrey and Jackson, with whom he returned to Paris. This tour called forth a volume of *Rhymes on the Road*—miscellaneous pieces of unequal merit, but embodying the poet's impressions of the magnificent ascent of the Simplon, the appearance of Venice, and the glories of ancient art.

Moore,
Thomas.

On all such subjects the inferiority of Moore to Byron, thus made apparent, was strikingly manifest. Some reviewing for Jeffrey, and some additional Melodies for Power, helped to supply the exigencies of life in Paris; but Moore's celebrity and multifarious acquaintance were fatal to anything like severe study. Had he taken refuge in Holyrood he would have been saved many temptations, but he would also have missed much enjoyment; and his satirical poetry would perhaps have lost some of the Attic point and polish which familiarity with high life and public affairs in different countries was fitted to impart. At length, in September 1822, Moore received the welcome intelligence that he might safely return to England. The Bermuda claims had been reduced to a thousand guineas: towards this sum the uncle of the deputy contributed L.300, and the Marquis or Lansdowne deposited the remaining portion (L.750) in the hands of a banker, to be in readiness for the final settlement of the demand. Moore allowed the deposit to be thus applied, but immediately reimbursed his noble friend by a cheque on his publishers for the amount. And thus the harassing claim which had hung as an ominous cloud over the poet's household for more than three years was easily and independently liquidated.

The first publication of Moore, after his return to his Wiltshire cottage, was another romantic poem, *The Loves of the Angels*, founded on eastern story and rabbinical fictions, that allegorized the fall of the soul of man from its original purity. He next resumed satire in poetry and prose, having published *Fables for the Holy Alliance* (1823) and *Memoirs of Captain Rock* (1824). The latter is a lively epitome of Irish history, in which, under the name of a celebrated Irish chieftain, he detailed the violence and insurrection that had sprung from systematic oppression. Though bearing the character of a party pamphlet or special pleading, this volume evinced considerable research and a happy talent for dealing with historical and statistical facts. The same qualities were more strikingly displayed in his *Life of Sheridan*, published in 1825. As a work of contemporary history and biography, illustrated by personal anecdote and criticism, Moore's *Life of Sheridan* told much that was new and interesting; it was fairly and candidly written, presenting passages of powerful reasoning and eloquence; and was only objected to on the ground that it was too full of ornament and metaphor, the author having intruded poetry into the sober domain of historical prose. His next work was still more ornate, but there embellishment was graceful and appropriate. *The Epicurean, a Tale*, published by Moore in 1827, is the story of a young Epicurean philosopher who, in the reign of Valerian, visits Egypt, falls in love with an Egyptian maid, and ultimately, through her counsels and martyrdom, becomes a convert to Christianity. The philosophy and pathos of this little tale, and its exquisite descriptions, render it unique and unrivalled for brilliance among our works of fiction.

In 1830 appeared *The Letters and Journals of Lord Byron, with Notices of his Life*, by Thomas Moore, 2 vols. 4to. Thus modestly was ushered into the world a work that had cost Moore infinite trouble and anxiety, and which forms by far the most important and valuable of his prose productions. The noble poet had written memoirs of his own life—an autobiography, more or less complete, up to 1820—which he presented to his friend for publication after his death. Pressed as he always was by pecuniary necessities, Moore in 1821 sold the Byron manuscript to Mr Murray for 2000 guineas. In 1824 that event occurred which fell upon all Europe with grief and surprise—Byron suddenly died; and his friends became alarmed on account of the disclosures that might be made in the memoirs. Mr Murray expressed his willingness to give up the manuscript on repayment of his money with interest, and Moore unhappily was led into an arrangement by which the 2000 guineas were refunded,

Moore,
Thomas.

and the manuscript reclaimed and burnt. That he acted from honourable and chivalrous feelings cannot be doubted. The pecuniary loss was to him a heavy sacrifice; but it must ever be matter of regret that he was precipitated into such a step. Byron had intrusted his defence to his hands; he owed a solemn duty to the memory of his friend and benefactor, and the public had a right to know

What desolating grief, what wrongs had driven
That noble nature into cold eclipse.

Whatever was objectionable in the memoirs (not amounting, according to Lord John Russell, to more than three or four pages) could easily have been expunged, or the publication might have been deferred for years, like the memoirs of Walpole, but now all was lost; and the rash act of destruction was equally a fraud on the memory of Byron and on the public. But though thus swayed by a fastidious delicacy and deference to Lord Byron's family and early friends, Moore was afterwards enabled to erect a suitable and lasting memorial of his friend. His *Life of Byron* is one of the most interesting and instructive of biographies, conceived in a right spirit, and executed with singular ability, care, and judgment. Considered merely as a composition, this work deserves, as Lord Macaulay has remarked, "to be classed among the best specimens of English prose which our age has produced." And as the fame of Moore was thus placed on its highest pinnacle, his fortunes were no less benefited. For the copyright of the *Life* Mr Murray gave the large sum of 4000 guineas, besides furnishing no inconsiderable part of the letters and journals with which the work is enriched.

With the *Life of Byron* may be said to close the happy and brilliant portion of Moore's literary career. He still held on his course, however, though with subdued vigour, and, until his faculties were clouded by mental disease, was rarely a day without some effort at composition. His social celebrity also continued. In 1831 he published a slight poetical performance, *The Summer Fête*, commemorating a holiday gathering at Boyle Farm in Ireland; and the same year he issued *Memoirs of Lord Edward Fitzgerald*, the weak but amiable victim of Irish insurrection. In 1833 he ventured on a polemical, but to him congenial, subject, *Travels of an Irish Gentleman in Search of a Religion*. Moore, though indifferent to mere forms of faith, still adhered to his old Roman Catholic creed, and vindicated what he conceived to be its superiority to all others in truth and antiquity. In 1835 appeared the first volume of his *History of Ireland*, written for Lardner's *Cyclopædia*, and extending to four volumes. He bestowed pains and research on this work, but without success adequate to his labour: it was too long and close for a popular digest, yet not sufficiently critical or learned to render it an authority on Irish history. In 1841 and 1842 he collected his poetical works, writing short prefaces to each volume, and adding some additional verses. He still occasionally threw off a squib or song, and he contemplated writing the life of Sydney Smith, a task well suited to his powers had it been required ten years earlier; but disease was now dealing with the accomplished and indefatigable worker. A softening of the brain took place, as in the cases of Swift, Scott, and Southey, and he sank by slow degrees into a state of helpless infirmity and childishness, though happily free from pain. The latter years of the poet had been darkened by domestic grief and calamity. His three children had predeceased him—one of his sons having by his imprudence seriously embarrassed his father, and occasioned to both parents the most poignant distress. In 1835 a pension of L.300 per annum was conferred on Moore, and in 1850 a pension of L.100 was settled on his wife, "in consideration of the literary merits of her husband, and his infirm state of health." The poet lingered on for two years longer, lost to the world, and died at Sloperon Cottage on the 26th of February 1852, being

then in the seventy-third year of his age. It is a touching and characteristic trait of his last illness that he "warbled" or sung on the day of his death.

The *Memoirs, Journals, and Correspondence* of Moore, edited by Lord John Russell, have been published in eight volumes; and a volume of *Notes* from his letters to his music-publisher James Power, has also been given to the public. The best excuse for the voluminous, unconnected, and unsatisfactory work of Lord John Russell, is the fact that Moore left his papers for publication by his noble friend in order that some provision might be made for his family after his decease; and that Lord John obtained for the MSS. a sum of L.3000, which was invested for the benefit of the poet's widow. Lord John did little as editor; at least one-half of the diary should have been thrown out, and explanatory notes added to much of the remainder, if not the whole recast; but what he has written of his friend is honourable to his taste, judgment, and feelings. From the diary and other biographical materials we know more of the Irish poet, of his outer and inner life, than of any other of his illustrious contemporaries. His daily round of existence was of a very uniform tenor. His mornings were chiefly spent in study, his best poetry being composed in his garden or in the neighbouring fields. His evenings were devoted to society, and no poet—not even Pope—ever lived more among the great. In the country he enjoyed the refined intellectual hospitalities of Bowood; in London his company was eagerly courted in all circles. His table was covered with invitations. Authors, artists, booksellers, and musicians, ran after him. His journal for weeks together, through successive years, is little else than a record of morning visits, dinners, balls, the opera and theatres. The time and money thus spent kept him perpetually in difficulties. He could rarely leave home without forestalling the fruits of his brain by drawing on the Messrs Longman, on Power (his friendly banker on all occasions), or on the editor of the *Times*, and his literary tasks were in this way often delayed, and at last hurriedly finished. He saw the folly of such a course of splendid dissipation, and throughout it all he retained a relish for the quiet pleasures of home. But he could not resist the fascination of popular applause—the tumultuous delight with which his presence was hailed by the great, the beautiful, the witty, and accomplished; and the tears which were profusely shed over the songs he sung with so much sweetness. Never was vanity more fully gratified, or life more thoroughly enjoyed. No shadow could remain long on so bright and sunny a nature—his elastic gaiety of spirit was an overmatch for fortune! With most men this kind of existence would have led to a coarse unamiable selfishness; it did so with Sheridan and Byron, and we do not say that Moore escaped from it without injury—his vanity, like his demands on publishers, was apt to be exorbitant and unscrupulous. It was too much at times for his truth and affection. But altogether Moore was a man cast in a kindly, generous, and happy mould. In his intercourse with the great, though fed with soft flatteries all day long, and "dearly loving a lord," as Byron said, he preserved in a remarkable degree his independence, his frank cordiality, and freshness of feeling. He was, like Pope and Gray, devotedly attached to his mother (to whom he wrote two letters a week), he loved his wife and children, took a warm interest in all cheap and innocent pleasures, and tried to make every one about him happy. His love of Ireland was a principle or passion of a nobler stamp. *Her* he served with all his soul and strength, uplifting her banner in the hour of darkness and danger; and with the names of Grattan and Curran as Irish patriots, that of Thomas Moore will be for ever associated. (R. C—S.)

MOORS, the Arabian conquerors of Spain, well known by this name on account of their having come directly from the land of the ancient *Mauri*, or *Mauretania*. They first

Moors.

Moorshedabad. invaded the Spanish territories in 711 under Tarik, the lieutenant of Musa Ibn Nosseyr; and in 712 that able general, landing his forces, speedily completed the conquest that had been begun, and subdued the entire country, with the exception of the mountainous districts of Asturias and Galicia. (See MUSA.) The conqueror then assumed the reins of government in subordination to the viceroy of Africa, and was the first of the amirs who ruled the country for the next forty-four years. In 756 Abd-el-rahman, a military adventurer, and a descendant of the deposed Mohammedan dynasty of the Beni Ommiyah, won the supreme power by the sword. Till 1031 he and his descendants reigned as sovereigns of Spain. The local governors then threw off their allegiance, and established themselves as independent potentates. A series of civil wars, however, left Mohammedan Spain, in course of time, under the power of a few great kings. The Christians also, taking advantage of the internal dissensions of their Moorish enemies, marshalled themselves under Alfonso "the Battler," and captured Castile, and its capital Toledo. They were pursuing their conquests in 1086, when Yusef Ibn Tashfin, a member of that religious sect, called the Almoravides, which had already subdued Northern Africa, suddenly appeared to retrieve the sinking Moslem cause. In the same year Alfonso was defeated at Zalaca, and the progress of the Christians was checked. Yusef was raised to the sovereignty of the country in 1099; but the Spanish dynasty of the Almoravides which he founded lasted only for a few generations. The Almohades, another religious sect from Africa, invaded Spain, and in 1146 the sceptre passed into their hands. During their sway the Christians continued to extend their conquests over the territory of the Moors until 1238, when Mohammed Ibn Alahmar, King of Granada, became the vassal of Ferdinand III., King of Castile. From this date the Moorish cause steadily declined beneath the attacks of the Christians, and the still more fatal attacks of a continuous series of treacherous conspiracies and internecine broils. At length in 1491 Ferdinand V., King of Castile and Aragon, captured Granada, and gave the death-blow to the power of the Moors. (See SPAIN.)

MOORSHEDABAD, a city of Hindustan, in the district of the same name, and province of Bengal, of which it was at one time the capital. Its original name was *Muksoosabad*, but this was changed to its present denomination. It extends, including Cossimbazar, eight miles on both sides of the Bhagiratty or Cossimbazar River, a branch of the Ganges, about 120 miles above Calcutta. It is a modern city, and was never fortified, excepting by an occasional rampart in 1742, during the Mahratta invasion. The streets are narrow and inconvenient, inasmuch that they are impassable for European carriages. The buildings are in general bad. Most of the houses have only one storey, with tiled roofs; and the palace of the nawaub is so insignificant as to be passed without observation. From the market-place runs a long, narrow, winding street, composed of mean houses and huts, which is again intersected by others still more narrow and miserable. The sewers originally intended to carry off the water having been destroyed, the streets become nearly impassable after a heavy fall of rain, and emit putrid effluvia. In the year 1813 a canal was dug between the Bhagiratty and the great Ganges rivers, which, independently of its commercial benefits, tended to ameliorate the unhealthiness of the town. But notwithstanding these exertions, it was remarkably unhealthy in 1814, and many Europeans suffered in the general mortality which prevailed. A strong desire is stated to have been manifested by the present nawaub for the im-

provement of its sanitary condition. It is still, however, a place of great inland traffic, and the river is constantly covered with boats. A Mohammedan college was some years since founded here, to which an English professorship was subsequently attached. In 1757 Moorshedabad was superseded as the capital of Bengal by Calcutta. Long. 88. 15. E., Lat. 24. 12. N.

The district of which this place is the chief town has an area of 1856 square miles, and a population estimated at a million of inhabitants. Before the commercial charter of the East India Company had ceased, this district was the principal seat of its silk manufacture. The production and manufacture are still carried on by private individuals. The principal silk manufacture is that of Corahs. The dignity of the Nawaub of Moorshedabad, which has become purely titular, is supported by the grant on the part of the British government of the magnificent allowance of L.160,000 per annum. Shah Allum, the Emperor of Delhi, conferred the territory upon the East India Company by the grant of the Dewanny in 1765.

MOOSH, a town of Asiatic Turkey, capital of a small pashalic of the same name, under that of Erzeroom. It is pleasantly situated on the summit and sides of a conical hill, near the Murad Chaï, or eastern arm of the Euphrates, 75 miles S.S.E. of Erzeroom. The plain in which it stands is about 40 miles in length by 12 or 14 in breadth, and has an elevation of 4692 feet. It is well watered, though in some places dry and stony; and its climate is one of extremes. It contains about 100 villages; and produces grain, tobacco, and wine, the last being of good quality. The town itself has a wretched appearance, and is inhabited by Turks and Armenians, the latter of whom, having the whole trade of the place in their hands, are the wealthier class, and pay an annual tribute of about L.2000, from which the Turks are exempt. There are 7 mosques, 4 churches, and several large and well-stocked bazaars in the town. Coarse cotton cloth is manufactured here. The principal articles of export are tobacco and cattle; while a very small amount of European manufactures is imported. Pop. estimated at 6000.

MORA, a town of Spain, in the province of Toledo, 18 miles S.E. of Madrid. The streets are wide, but unpaved; and there are three market-places. The town has a church, a town-house, a prison, and several schools. The inhabitants are chiefly employed in agriculture, in the manufacture of articles from rushes, in flour and oil mills, and in soap-works. Pop. 5094.

MORADABAD, a town of Hindustan, and the principal place of the British district of the same name. It has considerably declined from its ancient consequence, having been the seat of a mint in which rupees were coined, which were current in Hindustan, until superseded by the new rupee of the East India Company. It is 838 miles N.W. from the city of Calcutta. The population, according to the latest official return, is 57,414, the majority of which is Mohammedan. The district of which this town is the chief place has an area of 2967 square miles, and a population of 1,138,461. The province was ceded to the East India Company in 1801 by the Nawaub of Oude. The town of Moradabad is in Lat. 28. 49., Long. 78. 50.

MORAL-DE-CALATRAVA, a town of Spain, in the province of Ciudad Real, is situated on the edge of the sierra of San Cristobal, 17 miles S.E. of Ciudad Real. The houses are generally low; and the town contains a church, town-house, prison, hospital, and several schools. There are also several flour and oil mills, and manufactories of cloth. Pop. 4120.

Calatrava.

MORAL PHILOSOPHY.

INTRODUCTION.

Introduction.

1. MORAL PHILOSOPHY is the science of *what ought to be* in human character and conduct. In this lies its fundamental idea, and by this is described the object with which it is versant. Whilst other sciences relating to man aim at the scientific theory of what *is*, Moral Philosophy has for its special province and aim the scientific theory of what *ought to be*. "The *quid est*," says Dr Chalmers, "is not to be confounded with the *quid oportet*; and moral truth is in every way as distinct from the facts or principles which make up the actual constitution of the human mind, as mathematical truth is distinct from the laws and properties of the material world. The question, What are the affections or purposes of the mind? is wholly distinct and dissimilar from the question which relates to the rightness and wrongness of those affections and purposes. My knowledge that such a purpose or passion exists is one thing; my judgment of its character is another. In the one case it is viewed historically as a fact; in the other case it is viewed morally as a vice or a virtue. In the one case it belongs to mental, in the other to moral science."¹ Generally, moral science proposes to determine the grounds on which moral distinctions rest; the criterion or standard of rightness and wrongness in actions; the nature, conditions, and principles of virtue; the place and operations of conscience in the human economy; the laws and divisions of duty; and, in short, all that goes to the determination of what man has to be and to do in order to acquit himself of the obligations under which he has been laid by God.

2. The proper object of this science is *actions*,—meaning by that term all that results from the energy of volition.² Whilst Psychology contemplates what is given in consciousness simply as phenomenal, and aims at discovering the laws under which the facts so obtained may be reduced, Moral Philosophy goes out upon the field of man's active life, and by a standard previously fixed, determines what actions are good and what bad; and thus dictates what course of conduct it behoves man to follow.

3. All human actions, however, do not fall within the province of this science. The Greeks distinguished between *πράξεις* and *ποιήσεις*, *doings* and *makings*; though all do not agree as to the limits of the distinction. Without entering here on these differences, we may content ourselves with what Aristotle says on the subject:—"The end of *making* (or production) is different (*i.e.*, from the making itself); but of *doing* it is not so, for the well-doing itself is the end."³ "Making and doing differ specifically from each other. . . . Now life is a doing, not a making."⁴ "Prudence has to do with practice,—that is, with things which are the object of choice or aversion, and which it rests with ourselves to do or not to do. Nor is the faculty

Introduction.

for doing and the faculty for making the same; for the latter has an end distinct from the making, as in the building art, where, since there is the making of houses, an end distinct from the building itself—namely, the house—is proposed; and it is the same with the joiner's art and others that have to do with making. In respect, however, of the practical, there is no other end besides the doing itself, but the very energy and action is the end. Hence prudence has to do with practice and practical things, but not with making and things made."⁵ These passages seem sufficient to establish that the distinction between these two, in the mind of Aristotle, was determined by the fact, that the one class of actions is prompted by the emotive principles of our nature, and terminates in the satisfaction of the particular desire or passion by which the action is prompted; whilst the other class is more under intellectual control, and finds its terminus in the production of something distinct from itself. This is the distinction between moral conduct and productive activity; and it serves to define still more closely the boundaries of our science. Moral Philosophy has to do with those actions which are directed to the gratification of the emotive principles of our nature; it has nothing to do immediately with those actions the end of which is production, though mediately and indirectly it may have to do with these, inasmuch as they are sometimes the instruments by which the gratification of the desires is secured or sought. With the building of a house it has no concern; but it may have much to say in reference to the *proposal* to build it, the *end* for which it is built, and the *relations to each other* of those engaged in building it.

4. Of those actions which fall within its sphere Moral Philosophy has to determine the *rightness* or the *wrongness*, and consequently to indicate what practices are to be followed and what shunned. This, however, presupposes some standard of rectitude by which the moral character of actions may be determined; and this again presupposes a ground or basis of moral distinctions on which this standard rests. Before proceeding, therefore, to delineate a scheme of practical rectitude, it is necessary to institute an inquiry into the nature of rectitude itself, and to ask what its true basis or primal reason, and what its just and fittest standard.

5. An action implies an agent; a moral action a moral agent. The consideration of moral actions, therefore, naturally leads to the consideration of moral agents; and here the question which arises is, In what relation do moral agents stand to rectitude? The solution of this question involves an inquiry into man's moral constitution, into the position he occupies as the subject of a moral government, and into what constitutes the virtue or moral excellence of one so placed.

6. Having determined these points, we may proceed to

¹ *Moral Philosophy*, ch. i., Works, vol. v., p. 15.

² Per humanam actionem intelligimus non quemvis motum a facultatibus hominis procedentem; sed illum duntaxat qui provenit ac dirigitur ab iis facultatibus quas humano generi præ brutis Creator O. M. attribuit, nempe qui velut prælucenti intellectu, ac decernente voluntate suscipitur. (Puffendorf, *De Officio Hominis*, book i., ch. i., § 2.)

³ Τῆς μὲν γὰρ ποιήσεως ἕτερον τὸ τέλος. Τῆς δὲ πράξεως οὐκ ἂν εἴη ἔστι γὰρ αὐτῇ ἡ εὐπραξία τέλος. (*Nic. Eth.*, b. vi., c. iv., § 3, Lancaster's edit.) The style of Aristotle is so very condensed, that it may be well to add the paraphrase of these words by one of his commentators:—"Addit Philosophus illam distinctionem quod actionis est alius ab ipsa finis, ut opus quod ars molitur: at actionis non semper est alius ab ipsa finis, cum ipsa perfecta ac absoluta soleat esse finis." (Ant. Riccoboni, in *Eth. Arist. ad Nic. Comment.*, p. 160, Oxon. 1821.)

⁴ Διαφέρει ἡ ποιήσις εἶδει καὶ ἡ πράξις . . . ὁ δὲ βίος πράξις οὐ ποιήσις ἐστι. (*Polit.*, b. i., c. 4.)

⁵ Ἡ δὲ φρόνησις περὶ τὰ πρακτὰ, ἐν οἷς αἰρεσις καὶ φύγη, καὶ ἐφ' ἡμῖν ἐστι πράξαι καὶ μὴ πράξαι. ἔστι δὲ τῶν ποιουμένων καὶ πραττομένων οὐ ταῦτ' οὐδὲ τὸ ποιητικὸν καὶ πρακτικὸν τῶν μὲν γὰρ ποιητικῶν ἐστὶ τὸ παρὰ ποιῆσιν ἄλλο τέλος οἷον παρὰ τὴν οἰκοδομικὴν, ἐπειδὴ ἐστὶν οἰκίας ποιητικῆς, οἰκία αὐτῆς τὸ τέλος παρὰ τὴν ποιῆσιν ὁμοίως ἐπὶ τεκτονικῆς, καὶ τῶν ἄλλων τῶν ποιητικῶν ἐπὶ δὲ τῶν πρακτῶν οὐκ ἐστὶν ἄλλο οὐδὲν τέλος παρ' αὐτὴν τὴν πράξιν, ἀλλ' αὐτὸ τοῦτο τέλος ἡ ἐνέργεια καὶ ἡ πράξις, &c. (*Magna Mor.*, b. i., c. xxxv.)

Introduc-
tion.

consider the practical course which the principles thus ascertained indicate as that which man ought to pursue. This is tantamount to an inquiry into the *duties* which devolve upon us as under moral government; for the sum of human duties comprises the whole of what, as an intelligent and accountable agent, man has to attend to.

7. "Every art and every method," says Aristotle, "likewise deed and choice, seems to aim at some good; wherefore the good is well defined to be that which all things aim at."¹ But if all the actions of men aim at some good, it becomes necessary to inquire what is the sovereign good or supreme end of human activity. This will be found to be happiness,—“our being's end and aim.” But if all men's actions are aimed at happiness, and at the same time must be in accordance with virtue, it becomes necessary to inquire in what relation happiness and virtue stand to each other,—whether they are identical, correlate, or subordinate the one to the other.

8. The science of Moral Philosophy thus branches off into four principal parts:—I. The theory of rectitude in actions; II. The theory of virtue in individuals; III. The scheme of practical duties; IV. The doctrine of happiness.

Obs. 1. Were the usage familiar in moral science which has been so extensively and with so much advantage followed in physical science, of naming separate branches by words compounded from the Greek, with *lógos*, discourse or science, we might conveniently denominate these four divisions of our science thus: I. *Orthotetology*, from *óρθóς*, rectitude; II. *Aretology*, from *ἀρετή*, virtue; III. *Deontology*, from *τὸ δεόν*, that which is binding or due; and IV. *Eudaimonology*, from *εὐδαιμονία*, happiness. Of these terms, some have been actually employed, and the others might with equal right be introduced.²

Obs. 2. To some it has appeared that there is no valid distinction to be taken between rectitude as a quality of action, and virtue as an attribute of individuals. Thus Dr Thomas Brown affirms, that “to say that any action which we are considering is right or wrong, and to say that the person who performed it has moral merit or demerit, are to say precisely the same thing;” and again, “the action, if it be anything more than a mere insignificant word, is a certain agent in certain circumstances, willing and producing a certain effect.”³ Many passages of similar import might be cited from his lectures, for he insists upon this point with an almost wearisome iteration. Now it may be admitted that to say “that action is right,” and to say of the man who performed it, “he has acted virtuously,” may often mean substantially the same thing; but it by no means follows from this that in both cases the mind is contemplating exactly the same object. Two forms of speech may convey the same general sense, and yet the things spoken of may not be identical. In the case before us the *action* is viewed in relation to a certain objective standard—that of rectitude; whilst the *agent* is viewed in relation to a certain subjective law—that of conscience. Moreover, though the rectitude of the action and the virtue of the agent may often concur, they are capable of existing separately. There may be virtue in the agent where the action itself is wrong; and there may be rectitude in an action where there is no virtue in the agent. This is so familiar a fact, that Dr Brown could not overlook it; but the way in which he endeavours to obviate the objection thence arising to his own doctrine is anything but satisfactory. Thus, in order to account for our approving an action as right, whilst we cannot approve of the individual who performs it, he supposes that we imagine the action as proceeding from a totally different individual, and as performed under totally different circumstances. Thus, it seems, we do distinguish between the action and the agent as respects moral worth, commending the one whilst we condemn the other. But we accomplish this by interpolating a second agent, an imaginary person, to whom we ascribe the action. The simple answer to this over-argute philosophy is, in the first place, that it is false in fact; for we do nothing of the sort affirmed; and

in the second place, that it is unsound in principle; for how could an imaginary person confer a character on a real act? If the act have no moral character apart from the agent, then an imaginary agent can confer only an imaginary character. Dr Brown was betrayed into this fallacy by his peculiar theory of morals, of which more afterwards.⁴

Introduc-
tion.

9. Moral Philosophy has often been extended so as to embrace other sciences, which, though closely allied to it, are yet capable of being investigated apart from it, and are most advantageously so investigated. Aristotle, who regarded morals as a branch of politics, describes the science as *ἡ περὶ τὰ ἀνθρώπινα φιλοσοφία*, “the philosophy pertaining to human affairs.”⁵ This is sufficiently comprehensive, and would bring under one science not only Morals, Politics, and Economics, but also Psychology, Logic, Rhetoric, and Æsthetics. This general statement, however, must be qualified by what the author elsewhere insists on respecting the distinction between *πράξεις* and *ποιήματα*. It will then appear that Aristotle regarded as the proper province of moral science those actions which arise from passion, desire, or affection, with all the social arrangements and relations to which they lead. He thus classes under one general science,—Ethics, or the science of personal conduct; Politics, or the science of the relations of citizenship; and Economics, or the science of domestic relations. To this arrangement no objection can be urged, so far as the *matter* of the science is concerned, provided it be understood that the relations of citizenship and of the household are considered only under their *moral* aspect, and apart from legal, fiscal, or prudential considerations; but it seems better to confine the *term* Politics to the science of social and civil relations, in so far forth as these are determined by positive enactments or customs; and the *term* Economics to the management of households or communities, in respect of their physical and financial interests.

A recent writer on Moral Philosophy has claimed for it a province nearly as wide as the words of Aristotle, in all their unqualified breadth, would assert. “The laws,” says he, “of which Moral Philosophy is in quest are the laws of human activity; the theory of that unceasing spirit of pursuit which every human action displays; the systematic view of all those various phenomena by which the instinctive restlessness of our nature is evidenced.”⁶ But if *all* human activity is to be included within the sphere of Moral Philosophy, this science will absorb the entire range of speculation and of art, leaving only the mathematical and physical sciences to be prosecuted as separate branches. That the author is prepared to assert this wide claim appears evident from his ranking not only Politics and Natural Theology under Moral Philosophy, but also Rhetoric, Poetry, and Logic, all of which “have their foundation in the active nature of man.” It is difficult to see, however, what is gained by this clubbing of sciences, the materials and methods of which are different. It is no doubt true that all sciences which investigate the laws of human performance “have their foundation in the active nature of man;” but this is no more a reason for all these being reduced under one head, than the fact that all knowledges have their foundation in the intellect, is a reason for *every* science whatever being treated as a branch of Psychology. There is surely a wide and essential difference between performances which terminate on an intellectual composi-

¹ *Nicom. Eth.*, at the beginning.

² Thus there is a work entitled *Aretologie, oder Philosophische Tugendlehre*, by Wilh. Traug. Krug; another, entitled *Aretologia*, by Dr Innes; and Bowring has designated the book in which he unfolds the ethical system of Bentham by the title of *Deontology, or the Science of Morality*.

³ Aristotle distinctly recognises the distinction between rectitude in actions and virtue in the agent. Compare, e.g., his reasonings in chapter iii. (iv.), book ii., of his *Nicom. Ethics*, where he argues that a man cannot become a good man simply by doing what is good, as he may become a musician simply by playing tunes; “for,” says he, “it is not with virtues as with arts; in the latter the doing of the thing is what is required,—it is enough if anyhow it be done; but in the former it is not enough that the thing be done,—it is also required that the doer of it be rightly affected,” &c.

⁴ Hampden, *Course of Lectures introductory to the study of Moral Philosophy*, p. 76.

⁵ *Nicom. Eth.*, b. x., c. iii., p. 350 of Lancaster's edit.

Introduc-
tion.

tion or a physical structure, and performances which terminate in the gratification of a desire, the manifestation of a disposition, or the development of a character. The laws which these two different classes of energies obey, the methods by which these are to be discovered, and the uses to which they are to be applied, are so different, that not only may they be studied apart, but it is for the interests of both that they should be so studied.

The teaching of Moral Philosophy, as comprehending the science of Mind as well as of Morals, has been complained of by Dr Chalmers as an evil connected with the scheme of instruction pursued in the Scottish universities, where, says he, Moral Philosophy has been made to embrace, along with its proper object, "the whole physiology of the mind, with all its feelings and all its faculties;" and also "the laws and methods of the human understanding."¹ The published writings of Reid, Stewart, and Brown go to corroborate this statement; for all of these philosophers, though occupants of the Moral Philosophy chair, deemed it their province to devote a large portion of their lectures to mental science, including Psychology, Æsthetics, and Logic. Practically the only disadvantage resulting from this arrangement has been, that too heavy a burden has been "laid upon one solitary professorship;" for by none of these eminent men, nor by any of their colleagues or successors, has the mistake been committed of in any degree confounding the two great branches of knowledge which their course of lectures was made to embrace. Nor has the union of the two in the prelections of one teacher been without its advantages. Important as it is to keep the branches distinct, it is yet possible to make the separation between them too precise and too broad. Mental Philosophy is not the science of morals, nor Moral Philosophy the science of mind; but nevertheless there can be no doubt that the two are closely related, and that it is not desirable that he who would accurately apprehend the one should wholly pretermit, or only carelessly scan the other. Part of the field is common to the two, in so far at least as the objects of study are concerned; for the whole of the emotional or conative part of our nature belongs alike to Psychology and to Moral Philosophy. Still, the two provinces are distinct; and whether cultivated by the same parties or not, they are best treated of as separate knowledges.

Moral Philosophy has also been sometimes extended so as to embrace Casuistry, Jurisprudence, and Political Philosophy. With these it undoubtedly stands closely associated; still they are not to be confounded with it. Paley says that Moral Philosophy and Casuistry "mean the same thing;"² but it is not so. The two differ as Mechanical Philosophy differs from the art of the mechanician; the former having for its end the establishing of the principles of morals, the latter having for its end the application of these principles to difficult cases, such as actually or potentially lie within the sphere of individual experience, especially such as seem to involve an apparent collision of duties.³ Moral Philosophy has this in common with Jurisprudence, that both have to consider man in relation to *jus*; but in the former it is *jus* as determined by the unwritten law of nature, that comes into consideration; in the latter it is *jus* as expressed in statutes and conventions, that forms the subject of inquiry. Moral Philosophy has to expound the duties of man as a member of civil society, and therefore comes very close

Introduc-
tion.

upon the province of Political Philosophy; but it belongs to the latter exclusively to examine the structure of governments, and to determine their comparative advantages in relation to the main end of government,—a subject sufficient in extent, variety, and importance, to entitle it to become the topic of a special science.

10. The ancient Greeks gave to the science of Morals the title of *Ethics*, ἠθικά, from ἦθος, *mos*; and this term has been much used by modern writers. It has been objected to, on the ground of being not sufficiently comprehensive, by some writers, who would confine it to that part of moral science which has to do with the intercourse of individuals in private life. Thus Bishop Hampden objects to it on the ground that, by adopting it we exclude Natural Theology and Politics from the domain of Moral Philosophy.⁴ To this conclusion he and others have been led by unduly attending to the mere etymological force of the word. It seems, however, to have escaped them, that, on the same ground, we ought to discard the term *moral*; for "moral" is the synonyme of "ethical," with this difference, according to Quintilian,⁵ that ἦθος involves more the idea of rectitude than *mos*, and is consequently the firmer root of the two from which to form a designation of the science of right conduct. But in all cases of this sort etymology can be allowed very little weight in determining the sense and compass of the terms. Here usage, "quem penes arbitrium est et jus et norma loquendi," must be allowed its full rights; and the same authority which extended "moral," so as to make it embrace all questions relating to man's duty and obligations, can give the same extension to the term "ethical." If, then, it shall be found convenient to employ the term Ethics instead of Moral Philosophy, it only needs usage to sanction the change to justify its being adopted. To us it appears that this necessary and authoritative sanction has been given, and we regard it as desirable that the change of terminology thus justified should be followed. The convenience of the change is the least of its advantages. In addition to this, by using the term Ethics we not only follow the analogy of cognate sciences,—such as Metaphysics, Dialectics, Æsthetics,—but we set free the term Moral to be used, in its antithesis to mathematical and material, as comprehensive of all the sciences resting upon probable evidence; and more than this, we obtain for our own science a more just and exact appellation than that we would supplant. On this last point the following observations from the pen of one of the ablest living thinkers of Germany are worthy of consideration:—"The best name for this science is Ethic, or doctrine of morals (*Sittenlehre*), as is clear from the relation of this word to the three fundamental concepts of morals,—Law or Duty, Virtue, and Chief Good. *Mos* or *mores* (whence *Disciplina Moralis*) respects rather the outward phenomenon than the inner source, and is not commensurate with the Greek ἦθος. *Mores* denotes, indeed, the character, but not the comprehensive source; whilst, on the other hand, ἦθος, originally the Ionic form of ἔθος, includes the habit, the appertaining conduct; and that not merely as an empirical manner (*mos*), which may be evil, but as what is sanctioned, what is according to order and rule. As the word, however, denotes that in which one is at home, in his element (ἔθος is allied to ἔδος and ἔζω, as *sitte*, custom, is to *sitzen*, to sit, so that the *ethos* denotes the inner ground-tone), it

⁵ *Lectures*, pp. 36, 37.

Introduc-
tion.

follows that it embraces, along with the objective law, still more definitely the subjective living conditionality, which, as good, is virtue,—consequently what we term morality (*sittlichkeit*); whilst good-breeding, decent behaviour (*sittigkeit, sittsamkeit*) express only the scrupulous conformity to social customs presumed to be good. But not only is there an *ethos* of individual persons, but also of communities,—for instance, in the family spirit; nay, the moral which specifies itself in moral communities has in the *ethos* of these its subsistence, its subjective-objective being, so that also the concept of good is incorporated with the words *ethos* and *ethic*, and so there lies therein also the transition to the forms in which the highest good is presented.”¹

11. By some Moral Philosophy has been regarded as a branch of Theology; while others have proposed to treat Natural Ethics and Christian Ethics as distinct subjects. Instead of adopting either view, it would be probably better to restrict Theology to the investigation of what has been revealed to us concerning God and his methods of dealing with his creatures; whilst Ethics would be versant with man’s moral relations to God, and to those creatures of God, with which he is in any way connected. And in exploring this field, it seems wise neither to overlook what the Scriptures inculcate respecting man’s moral relations and duties on the one hand, nor on the other to count it sufficient simply exegetically to expiscate from the sacred page a list of moral truths, without referring them to their philosophical basis, or assigning them their proper place in a scientific system. There is one department, however, of scriptural Ethics which must be suffered to fall under the head of Theology,—viz., that which embraces the special duties arising to the Christian, as such, out of the new relations into which the extraordinary scheme of human redemption brings all those who enjoy its benefits. This, in the strictest acceptation of the term, is *Christian Ethics*, because setting forth duties binding, not on man as man, but on such men only as are partakers of the redemption which is in Christ.²

12. Moral Philosophy is not to be ranked among the inductive sciences. From observing the moral constitution of man we may indeed draw the conclusion, that the final cause of such a constitution is, that man should be under moral government; but we cannot by this process discover what constitutes morality, what lies at its basis, or what expresses its principles. As little could we construct a system of Ethics from merely observing the conduct of men, or collecting their opinions on moral questions: at the utmost this would only enable us to declare empirically what they for the most part may have agreed to regard as morally right or wrong; it would give us no criterion by which to determine scientifically whether the judgment so reached was the just one. The question, “*Quid oportet?*” is one “to the solution of which,” as Dr Chalmers observes, “we are guided by another light than that of experience. This question lies without the domain of the inductive philosophy, and the science to whose cognisance it belongs shines upon us by the light of its own immediate evidence.”³ “By induction,” says another writer, “from particular observation of what transpires in our own minds, we may indeed ascertain that we are accountable; that we possess those powers or faculties which are presupposed in a system of moral agency; and that, according to the kind of conduct pursued by us is our happiness or the contrary, or at least the approbation or disapproba-

Introduc-
tion.

tion of our own conduct. But from observation of what transpires within us merely, we can never by any process of induction arrive at a knowledge of the true nature of virtue and vice, or of their respective sources. We cannot in that way discover the standard by which good and evil are measured, the grounds of obligation to pursue the one and avoid the other, the causes on which success or failure in that pursuit depend, or the means to be adopted in order to the practice of virtue and the attainment of happiness. The very supposition that such a method of constructing a true moral philosophy can possibly succeed, must assume that the inquirer is in fact a perfect being—that what ought to be, and what is, are in him the same thing. How else, by any observation of his thoughts, feelings, volitions, and actions, can he ascertain the rule of requirement—the general law of rectitude?”⁴

13. For the successful pursuit of moral science it is important that the mind should be well disciplined in the analysis of moral phenomena; habituated to the weighing of probable evidence; accustomed at once to comprehensive views of things and to minute discrimination of differences; familiar with human nature, with men and their ways; and calm, deliberative, and sagacious in its processes of decision. Hence the inexpediency of including this science among the studies to be pursued by very young men. On this point the most eminent teachers of the science are agreed. “Beware, my dear,” says the Platonic Socrates to a youthful friend, “lest you risk what is most precious to you; for there is much more hazard in the purchase of instructions than in the purchase of food. When one has bought eatables or drinkables, he may carry them from the shop and market in other vessels, and before, by eating or drinking them, he receives them into his body he may, having deposited them at home, and having called in some skilful person, take counsel whether anything is to be eaten or drunk, and how much and when; so that in such a purchase there is no great risk. But there is no carrying of instructions in another vessel; he who receives them must pay the fee and carry them in his soul itself, and having learned, must depart either injured or profited. Let us then consider these things [moral questions] with our seniors, for we are still too young to adjudicate so great a matter.”⁵ Aristotle repeatedly forbids the young to occupy this territory. He bids them study mathematics, but exhorts them to leave politics and morals till they have gathered experience. “Youths may become geometers and mathematicians, and skilled in such [knowledge]; but it does not appear that a youth becomes wise [i.e., morally wise, *φρόνιμος*]. The reason is, that wisdom has to do with particulars which become known from experience; whence a youth is not experienced, since it is number of years that gives experience.”⁶ And in the earlier part of the same work he says,—“A youth is not a fit auditor of political science; for he is without experience of those actions which have to do with life; whilst the discourses [he would have to hear] are out of these and concerning these. Moreover, being disposed to follow his passions, he would hear in vain and without profit, since the end is not knowledge but action. It matters not, however, whether he be a youth in years or youthful in habit; for the defect is not in respect of time, but from his living and pursuing everything by passion, inasmuch as to such the knowledge becomes useless no less than to the incontinent. To those, however, who regulate their appetites, and who act according to rea-

tion.

son, it is most useful to know about these things."¹ To the same effect Burgersdyk writes, "Actiones civiles versantur circa singularia, de quibus non secundum præcepta sed secundum occasionem judicandum est. Quod certe fieri non potest, nisi ab eo qui longo rerum usu atque experientia prudentiam sibi comparavit; quæ in juvenibus admodum rara est."² To these testimonies may be added those of Stewart, and Hume as quoted by Stewart.³

14. In attempting to discuss a subject of so much importance, of such compass, and of such difficulty within such limits as this article must necessarily be confined to, we feel that we have imposed on us no easy task. Our aim chiefly shall be to present such a view of the subject as shall meet the wants of the learner and the general reader.

15. No attempt is here made to trace the History of Moral Philosophy, partly because the space allotted to this article renders it impossible to do anything like justice to such a theme; partly because the Preliminary Dissertations of Mr Stewart and Sir James Mackintosh to a great extent supersede the necessity of making the attempt. In lieu of this we shall content ourselves with laying before our readers a survey of the literature of the subject:—

PLATO. All the treatises of Plato are more or less ethical in their character and drift; of those specially devoted to this science the most important are,—the *Phædo*, the *Crito*, the *Gorgias*, the *Philebus*, the *Meno*, the *De Republica*, the *Politicus*, and the *De Legibus*. The most useful edition of his works is that of Stallbaum, of which only nine volumes have yet appeared. Gotha, 1837-1841. Other editions, with critical apparatus and notes, are those of Ast, 10 vols. 8vo, Leipsic, 1819-29; and of Bekker, 10 vols. 8vo, Berol. 1816-23. The Latin translation by Marsilius Ficinus (edited by Grynaeus, Basil, 1534, fol.), the German by Schleiermacher, and the French by Victor Cousin, are worthy of careful consultation. The standard English translation is that of Sydenham.

ARISTOTLE, *Ethica Nicomachea*, *Ethica Eudemea*, *Magna Moralia*, *Politica*, et *Economica*, and a [spurious] treatise, *De Virtutibus et Vitiis*. Of the Nicomachean Ethics, the best separate editions are those of Zell (Heidelberg, 1820, 2 vols. 8vo), Cardwell (Oxon. 1828-30, 2 vols. 8vo), and Michelet (Berol. 1819-35, 2 vols. 8vo). Very useful editions are those of Lancaster (Oxf. 1834), and Brewer (Oxf. 1836); the latter has English notes. Of the *Politica*, the editions of Schneider (Franf. 1809, 2 vols. 8vo), and Goettling (Jenæ, 1824), are reputed the best. The editions of his whole works most in repute are those of Pacius, 2 vols. 8vo, Genev. 1597; of Du Val, 2 vols. fol., Par., 1619; 4 vols., 1654; of Bekker and Brandis, 4 vols. 4to, Berol. 1831-36. Bekker's text was reprinted at Oxford, in 11 vols. 8vo, in 1837.

Introduc-
tion.

¹ *Nicom. Eth.*, b. i., c. i., § 11 (c. iii., near the end, according to the Pacian division).

² *Idea Philos. Moralit.*, &c., ed. 1644, p. 24. This is the "Dutch Burgersdyk" of the *Dunciad*, b. iv., l. 298.

"Each staunch polemic, stubborn as a rock,
Each fierce logician still expelling Locke,
Came whip and spur, and dash'd through thin and thick,
On German Crousaz and Dutch Burgersdyk."

Poets are not the best judges of the merits of writers on Logic and Metaphysics; and in these lines Pope has thrown an air of ridicule over two men who, as Hallam says (*Hist. of Lit.*, ii., 372), were famous in their generation, and may yet be listened to with advantage. Gibbon has owned his obligations to Crousaz (*Life*, p. 93 of Milman's ed.); and of Burgersdyk we may say, that in the departments of Logic and Ethics the incipient polemic or logician may spur many a less willing and useful steed.

PART I.—OF RECTITUDE.

SECT. I.—RECTITUDE DEFINED.

Rectitude. Rectitude is the conformity of actions to an acknowledged standard of right.

In all ages, and among all nations, a distinction has been recognised between right and wrong; and these qualities have been discriminated from other qualities with which they may frequently be closely associated, such as pleasant and painful, agreeable and repulsive, beneficial and noxious, &c. The proposition, "This is right," and the proposition, "This is agreeable," may be translated into all languages under the sun by appropriate synonyms; and by no people would they be accepted as conveying exactly the same concept. When Horace says of Homer,—

"Qui quid sit *pulchrum* quid *turpe*, quid *utile*, quid non,
Planius ac melius Chrysippo et Crantore dicit,"¹

it would be but a blundering translation which should confound the distinction expressed by the author between the *pulchrum* and the *utile*,—the morally fair or right (*τὸ καλόν*), and the useful (*τὸ χρήσιμον*). So also when Aristotle says of speech, that it is ἐπὶ τῷ δηλοῦν τὸ συμφέρον καὶ τὸ βλαβερόν, ὥστε καὶ τὸ δίκαιον καὶ τὸ ἀδίκον,² no person who understands his words will fail to make a clear distinction between the qualities contrasted in the first clause, and the qualities contrasted in the second,—between the profitable as opposed to the hurtful, and the just as opposed to the unjust.

In the words immediately following those just quoted Aristotle goes on to say, that man is the only animal to whom the perception of the distinction between good and bad, just and unjust, has been given. What man thus alone of all animals perceives, it has always been thought important by mankind prominently to enunciate; and hence among all nations we find this distinction expressed in the form of rules or maxims more or less precise and comprehensive; the sum of which constitutes for any community or body of persons the *standard* of right by which they measure the rectitude of actions. Hence rectitude is virtually what some of the ancients called it, νόμον πρόσταγμα, what the law prescribes, meaning by "the law" not any particular enactment, either by the state or by any corporate portion of it, but what the community at large regards as the standard of right and wrong; and what Mr Horne Tooke has said, with questionable correctness of right as an abstract quality, that the word "is no other than *RECT-um* (*regitum*), the past participle of the Latin verb *regere*," and that the *thing* means simply "that which is ordered,"³ may be accepted as not an inapt description of rectitude as a quality of actions. We may detect an analogous conviction in the use of the same words to designate the concept of *straightness* and the concept of *moral rectitude*,—a usage which is found to pervade all languages. When, in fine, we find the Hebrews denoting *sin* by such a word as חטא, and the Greeks by such a word as ἀμαρτημα, both derived from roots which signify primarily to miss a mark, and both used to denote the physical act of missing or swerving, we see a further evidence of how generally mankind have identified the idea of rectitude with that of conformity to some acknowledged norm or standard of right.

SECT. II.—RECTITUDE A REAL QUALITY.

Rectitude in actions presupposes and depends on a distinction between right and wrong *per se*; and the question, whether the quality so predicated of actions is to be regarded

as a *real* quality will be determined by the answer given to the question, whether this distinction is an essential and permanent, or only an accidental and variable distinction. That it is the former and not the latter, the following considerations render probable *in limine*:—

(i.) The recognition of the distinction by all peoples and in all times, as the appropriation of words to express it in all languages sufficiently indicates. A universal belief like this can be traced only to some common source of authority, the lessons of which the whole race has preserved from its cradle, or to convictions arising out of the nature of the case, and addressing themselves to every man's judgment. In the case before us the former hypothesis must be excluded as irrelevant (for however authority may attest a *fact* or establish a *principle*, it never can originate a subjective conviction); so that there remains only the latter hypothesis. But if the recognition of a distinction between right and wrong is to be traced to convictions springing into the minds of all men out of the nature of the case, this distinction must be one founded in nature, and therefore essential and permanent.

(ii.) The early period at which this distinction is recognised by children accords with the belief that it is a real and essential distinction. Anterior to education and experience a child will indicate, in the most unmistakable manner, its perception of the difference between what it thinks right and what it thinks wrong. This shows that the moral judgment is coeval with intelligence,—a fact which could not exist were the distinction on which that judgment proceeds one of an artificial or accidental kind.

(iii.) We find it impossible to conceive of right and wrong changing places, so that what is now right should become wrong, and *vice versa*. There is in this respect a rigidity which is peculiar to moral distinctions; for not only is it metaphysically impossible that rightness should become wrongness, just as it is metaphysically impossible that blackness should become whiteness, or crookedness straightness, but it is also physically impossible that the same object should become successively possessed of these opposite qualities. An object now black may become white, an object now crooked may become straight; but we cannot conceive of even omnipotence making that which is now right to become wrong. This, then, must be regarded as a distinction lying in nature, and immutable,—φύσει ἀκίνητον καὶ πανταχοῦ τὴν αὐτὴν ἔχον δύναμιν, as Aristotle expresses it.⁴

An ancient and favourite objection to this conclusion is drawn from the diversities that have obtained, at different times and among different nations, as to what is right and what is wrong. "Now to some," says Aristotle, "it appears that *all* are such (*i.e.*, made binding by arbitrary enactment); because what is by nature is immovable, and has everywhere the same power, just as fire burns as well here as in Persia; whereas they see that just things vary."⁵ "In the state of nature," says Hobbes, "nothing can be unjust; the notions of right and wrong, justice and injustice, have there no place;" and again, "The nature of good and evil varies according to the will of individuals in a state of nature, and of princes in every state."⁶ Locke has written to the same effect. "He that will carefully peruse," says he, "the history of mankind, and look abroad into the several tribes of men, and with indifference survey their actions, will be able to satisfy himself that there is scarce that principle of morality to be named, or rule of virtue to be thought on (those only excepted that are absolutely necessary to hold society together, which commonly, too,

⁵ Same place. See also b. i., c. i., § 9.

⁶ *Leviathan*, c. vi.

Rectitude. are neglected betwixt distinct societies) which is not somewhere or other slighted and condemned by the general fashion of *whole societies* of men, governed by practical opinions and rules of living quite opposite to others."¹

On these statements it may be observed—

(i.) That whilst there is undoubtedly ground for the fact alleged, the extent to which such variety of moral judgment prevails is apt to be greatly exaggerated by those who use it as an argument against the reality of the distinction between right and wrong. It may be questioned whether, if the whole human race were assembled, the variations of their judgments on questions of ordinary morality would exceed the ratio of one in a hundred; and as for Locke's assertion, that there is scarcely a single principle of morality or rule of virtue that is not slighted or condemned by whole communities somewhere, it can only be set down to the author's excessive zeal for the cause he had set himself to maintain. "But what nation," we may ask with Cicero, "loves not courteousness, benignity, a grateful mind, and one that remembers a benefit? What nation does not hate and spurn the proud, the maleficent, the cruel, the ungrateful?"² But if the mass of mankind agree in their moral judgments,—if the agreement be anything like that above suggested, in the ratio of one to a hundred,—it follows, that if the common consent of mankind proves anything in a case of this sort, it must be held as proving the reality and fixedness of moral distinctions. Surely a few exceptional cases are not to be allowed to nullify the general testimony of the race; nor are those minds to be envied that, from contemplating this, "can turn away to seek, in some savage island, a few indistinct murmurs that may seem to be discordant with the whole great harmony of mankind."³

(ii.) Even admitting the fact to the full extent alleged, it would by no means prove what it is adduced to prove. A principle may be universally recognised, though variably applied, and men may agree in holding a distinction to be real, though they may differ as to the objects by which that distinction is exemplified. In affirming the universal consent of the race to moral distinctions, it is not intended to maintain that all men apply these with infallible and unvarying accuracy. It is simply affirmed, that to the unbiassed judgment of men right appears right, and wrong appears wrong, and that this obtains always and everywhere. The variations which occur may be accounted for by accidental or partial influences. 1. Excessive emotion often tends to pervert the moral judgment. Under the irritation of violent passion acts frequently appear lawful and proper which, in more quiet moments, the party who is hurried into them cannot but condemn. Smarting from the sting of mortified vanity or disappointed ambition, even a good man may think he "does well to be angry." Blinded by prejudice and infuriated by hatred, the persecutor who hales innocent men and women to prison or to the stake, "thinks he does God service," and may even piously give thanks to God for the doom inflicted on those whom he deems in error; as Laud did when he "pulled off his cap, and, holding up his hands, gave thanks to God" when the barbarous sentence endured by Leighton was pronounced.⁴ In these and similar cases there is no perversion of the moral judgment properly speaking; there is simply a momentary suspension of the moral faculty, owing to the influence of something analogous to disease in the physical frame. 2. Some actions, in themselves indifferent, acquire a moral character only when they are performed under certain conditions; and consequently, in estimating the moral sentiments of the people by whom such acts are performed, we

Rectitude. must be careful to see that the requisite conditions exist. For example, to appropriate any article is an act which comes to possess a moral character only on the supposition that it is *property*; so long as it belongs to no one, to take it implies no wrong. In a country, therefore, where the distinctions of property do not exist, the natives may be found attaching no sense of impropriety to what, in the estimation of more civilized nations, would be regarded as stealing. But this does not prove that by these people dishonesty is not considered wrong; it only proves that they did not consider the act of helping themselves to what they did not regard as property to be dishonesty. Establish in their minds the conviction that the article they have appropriated belonged rightfully as property to another, and they will at once see the moral impropriety of depriving him of it.⁵ 3. It is seldom that acts can be contemplated under one simple aspect. Their aspects are generally numerous; and as under some of these aspects they may possess a different moral character from what belongs to them under others, it often happens that different persons or communities, from fixing their attention exclusively on different aspects of the same act, come to pronounce different moral judgments upon it. An act which under a certain aspect is wrong, may under another aspect be right, and *vice versa*; and hence may be tolerated, or even commended, by some, whilst denounced and condemned by others. Thus the slaughtering of innocent animals, if viewed under the aspect of an amusement, must be pronounced wrong; whereas, if viewed as necessary for the providing of food for man, it may be regarded as permitted; and if viewed as a sacrificial act, it may be commended as praiseworthy; so that three persons, viewing this one act from these three different points of view, might pronounce on its moral character three different judgments. This, however, would no more prove that the moral constitution or principles of these persons differed in each case than, in the famous shield case, the judgment of the one knight that it was black, and the judgment of the other that it was white, proved that their eyes were differently constituted, or that their notions of blackness and whiteness were not the same. This may serve to account for the fact, that many actions, in themselves of doubtful propriety, and many undoubtedly wrong, come to be regarded with approbation or indifference by individuals and communities: the actions have an aspect that is really or apparently harmless, and the parties fixing their attention only on that, and entirely overlooking the essential and primary aspect of the action, come to pronounce upon it an erroneous or defective moral judgment. It is upon this ground that Dr Chalmers so eloquently and forcibly accounts for the various cruelties which are practised, even in civilized society, upon the lower animals, whilst he denies that "even in the lowest walks of black-guardism," there is "such a thing as delight in suffering for its own sake."⁶ On this ground, also, may we account for the unnatural practices of infanticide and parricide, on which Locke lays so much stress in the context of the passage above cited from his *Essay*. No man, no people, but would condemn the slaying of a helpless babe, viewed simply in itself; but the slaughter of that babe may come to be regarded as a necessity imposed by the scarcity of provisions, or as the fittest means of averting some terrible calamity, or as upon the whole a kinder thing to the babe than to suffer it to grow up amidst pain, shame, or slavery; and in such cases the act, which in itself all would abhor, may come to be by some regarded as not only permissible, but even to a certain extent praiseworthy. It is the same where

¹ *Essay*, b. i., c. iii., § 10, Works, vol. i., p. 16, fol. ed.

² See Price's *Hist. of Protestant Nonconformity*, vol. ii., p. 69.

⁴ *Sermon on Cruelty to Animals*, Works, vol. xi., p. 249 ff.

⁵ *De Legibus*, i. 11.

⁶ Brown, *Lectures*, vol. iii., p. 592.

Rectitude. parricide is tolerated; the attention is withdrawn from the act in itself to certain concomitant or consequent effects which are desirable or commendable; and thus what no man would fail to pronounce wrong, if done apart from these effects, may come to be regarded as right when done for the sake of these. In all such cases there is no doubt perversion of moral judgment. But whence arises this perversion? Not from men regarding right and wrong as transferable qualities, but simply from their not viewing the act under that aspect under which alone its true moral character could be estimated. 4. The effect of education and custom must not be overlooked in reference to the variety of men's judgments as to the rectitude of actions. As the organs of taste may be taught to relish what to the uneducated palate is utterly nauseous, so may the moral faculty be educated to regard as lawful or good what the natural conscience would recoil from as sinful. Fashion, which can reconcile the æsthetic taste to the most inelegant costumes or the most grotesque combinations, is also sufficiently potent to reconcile the moral taste to practices altogether inconsistent with propriety and decency. "Who would believe," exclaims Charron, "how great and imperious is the authority of custom? To say that it is a second nature does not express all the truth; for it does more than nature—it conquers nature. . . . It dominates over our souls and our judgments with a very unjust and tyrannical authority. It does and undoes, authorizes and forbids, what it pleases, without rhyme or reason,—nay, oftentimes contrary to all reason; it makes valid and establishes throughout the world, against reason and judgment, the most fantastic and barbarous opinions, religions, beliefs, observances, manners, and modes of living; and, on the other hand, it injuriously degrades and vilifies things truly great and admirable, robs them of their worth and estimation, and renders them contemptible."¹ To the influence of this tyrannical power many of the differences which prevail among men, and which might at first sight seem to indicate a diversity of moral principle and judgment, may be traced. A practice is held innocent by some which all others hold wrong, simply because the tyranny of custom has in this one instance obscured their perception of right and wrong.² The influence, however, thus exerted by education and custom on the moral perceptions of men, though imperious, is partial and transient; were it otherwise, society could not be held together.³

SECT. III.—FOUNDATION OF RECTITUDE.

The considerations adduced render it probable that the distinction between right and wrong is a real and permanent distinction. But to determine this more precisely, it will be necessary to inquire into the *foundation* of this distinction.

On this point the conclusions at which inquirers have arrived are very different. These conclusions may be arranged under two distinct classifications; the former of which is determined by their relation to the question whether the distinction between right and wrong be a real one, the latter by their relation to the question whether this distinction is perceived by a judgment of the intellect or felt by an emotion,—in other words, whether the foundation of this distinction lies without us or within us. Com-

Rectitude. pounding these two classifications, we may present the following scheme of opinion on the point at issue:—

I.—EMOTIONAL OR SUBJECTIVE THEORIES.

- A.—Affirming the Mutability of Moral Distinctions.
 1. That right is what accords with desire; wrong what thwarts it.
 2. That right is determined by a special principle implanted in the elect.
- B.—Affirming the Reality and Permanency of Moral Distinctions.
 1. The theory of a Moral Sense.
 2. The theory of Conscience.
 3. The theory of Sympathy.
 4. The theory of Approbation.

II.—INTELLECTUAL OR OBJECTIVE THEORIES.

- C.—Affirming Moral Distinctions to be Accidental and Mutable.
 1. That they are created by human law.
 2. That they are determined by the Divine will.
 3. That they are determined by the consequences of actions.
- D.—Affirming Moral Distinctions to be Essential and Immutable.
 1. That they arise out of the fitnesses of things.
 2. That they are determined by the truth of things.
 3. That they are determined by the nature of things.
 4. That they lie in the essential nature of God.

Analysis may resolve some of these theories into a common principle; but as they have all been advocated by different writers, it may be proper, in the first instance, to consider them apart.

I.—*Emotional or Subjective Theories.*

A. 1 and A. 2.—On the first two theories in this scheme it is not necessary that we should dwell. They are, properly speaking, not so much attempts to account for the distinction between right and wrong, as attempts to set aside that distinction entirely. The former (A. 1) proceeds on the assumption that man is the slave of circumstances—that his desires are excited by extraneous objects, and that he must act as his desires prompt. The only good for man, then, is to have these desires gratified, and the only evil is to have them thwarted. What men call right and wrong is really tantamount to gratification and disappointment; or it is a distinction existing only in words, and meaning nothing in reality. The latter theory (A. 2), is that of the Antinomians, who maintain that the elect are endowed with a principle of action far beyond any law, and that as this principle always operates necessarily according to the Divine predestination, it invariably conducts to what is right, even though it may prompt to what, on the lower ground of legal morality, would be pronounced sinful or vicious. Such doctrines are chiefly worth noticing because they show the extremes to which men will go in devising theories when they wish to sustain some "foregone conclusion;" and also because, as compared with each other, these theories illustrate the tendency of extremes to meet, and show how the ultraism of theological speculation and the ultraism of infidelity may meet together and erect a common trophy on the ruins of morality.⁴ It is needless to linger on the refutation of either theory. The former is sufficiently refuted by the common consciousness and experience of the race, which loudly attest that man is not the slave of circumstances, that desire is not irresistible, that we have a conception of goodness and rectitude wholly distinct from that of desirableness, and that it is according as the one or the other of these

¹ *De la Sagesse*, b. ii., c. viii., § 6.

² "Tanta est corruptela malæ consuetudinis," exclaims Cicero, "ut ab ea tanquam igniculi exstinguantur a natura dati, exorianturque et confirmantur vitia contraria." (*De Leg.*, i. 12.)

³ See Smith's *Theory of Moral Sentiments*, part v.; Stewart's *Phil. of the Active and Moral Powers*, vol. i., p. 152, ff.; Brown's *Lectures*, vol. iii., p. 592, ff.

⁴ "If our Antinomians could pay a visit to the heathens of Hindustan, they would find millions on millions of their way of thinking. Nor need they go so far from home; among the apostles of modern infidelity the same thing may be found in substance. The doctrine of necessity, as embraced by them, reduces man to a machine, destroys his accountableness, and casts the blame of sin on the Creator. The body of these systems may be diverse, but the spirit that animates them is the same." (A. Fuller, *Works*, vol. ii., p. 599.)

Rectitude. predominantly regulates conduct that an individual is, in the common judgment of mankind, esteemed or despised. Of the latter theory, it may be enough to say that it is repudiated by the very authority on which its advocates base their entire scheme of speculation,—the language of Holy Scripture; for whatever ground Scripture may give for the belief that the elect are endowed with a special privilege of spiritual life, it most distinctly teaches that nothing can supersede the grand distinction between right and wrong, that the conduct of all men is amenable to the law of morality, and that those who boast of privilege, while they come short of rectitude, do but deceive themselves.

The theories forming sub-division *B.* of class *I.* are deserving of more careful examination. Though differing in detail from each other, they have this in common, that they propose to base rectitude on the existing constitution of the human mind. They differ as to the part of our mental nature which they select as furnishing the proposed basis, but they all agree in finding that basis among the facts given to us in consciousness. In proceeding to examine them, it is important to bear in mind, that with the psychological part of the theory we have here nothing to do directly; our whole concern at present is, conceding the alleged fact, to inquire whether in it a sufficient basis of moral distinctions is supplied.

B. 1. The first of these theories is that advocated in the writings of Professor Francis Hutcheson. We shall best explain it by citing the author's own words. "As the Author of Nature," says he, "has determined us to receive, by our external senses, pleasant or disagreeable ideas of objects, according as they are useful or hurtful to our bodies; and to receive from uniform objects the pleasures of beauty and harmony, to excite us to the pursuit of knowledge, and to reward us for it; or to be an argument to us of his goodness, as the uniformity itself proves his existence, whether we had a sense of beauty in uniformity or not; in the same manner he has given us a *moral sense*, to direct our actions, and to give us still nobler pleasures: so that, while we are only intending the good of others, we undesignedly promote our own greatest private good. We are not to imagine," he continues, "that this moral sense, more than the other senses, supposes any innate ideas, knowledge, or practical proposition: we mean by it only a determination of our minds to receive the simple ideas of approbation or condemnation from actions observed, antecedent to any opinions of advantage or loss to redound to ourselves from them; even as we are pleased with a regular form or a harmonious composition, without having any knowledge of mathematics or seeing any advantage in that form or composition different from the immediate pleasure."¹ In another work the author expounds his theory in the following terms:—"To regulate the highest powers of our nature, our affections, and deliberate designs of action in important affairs, there is implanted by nature the noblest and most divine of all our senses, that *conscience* by which we discern what is graceful, becoming, beautiful, and honourable in the affections of the soul, in our conduct of life, our words and actions. By this sense, a certain turn of mind or temper, a certain course of action and plan of life, is plainly recommended to us by nature; and the mind finds the most joyful feelings in performing and reflecting upon such offices as this sense recommends, but is uneasy and ashamed in reflecting on a contrary course. Upon observing the like honourable actions or designs in others, we naturally favour and praise them, and have a high esteem and goodwill and endearment towards all in whom we discern such excellent

dispositions; and condemn and detest those who take a contrary course. What is approved by this sense we count *right* and *beautiful*, and call it virtue; what is condemned we count base and deformed and vicious."² From these extracts the author's theory may be clearly ascertained. He teaches, that as our bodily senses convey to us "certain feelings, ideas, or perceptions, raised upon certain objects presented" of an external and material kind, and as our sense of beauty conveys to us certain pleasurable emotions raised by the perception of proportion or harmony; so our moral sense or conscience awakens in us certain emotions of satisfaction with what is becoming in conduct, and of displeasure with what is the opposite. Thus far the author has been only analyzing certain phenomena of a psychological character; and thus far his sentiments will probably be in substance assented to by all. But when he goes beyond this, and, as a moralist, refers our perception of moral distinctions to this moral sense or conscience, and still more, when he finds the basis of these distinctions in the feelings excited by this sense, he advances doctrines which are subject to the gravest objection.

It is with the latter of these doctrines only that we have at present to do; and on this it may suffice to remark, that in it the author has either wholly evaded the question at issue, or he has answered it by a *petitio principii*. It may be quite true that the perception of moral goodness excites in us a feeling of approbation, whilst the perception of moral evil excites in us a feeling of disapprobation; but by this statement the question, What *constitutes* moral goodness, on the one hand, and what moral evil, on the other? remains wholly unanswered; or it is answered by first assuming moral goodness to exist independent of the moral sense, so as to become the *object* of it, and then accounting for this existence by tracing it to the operation of the moral sense. In this latter case the fallacy is the same as if one were to affirm that it is the sense of smell which causes differences of odour, or the sense of hearing which causes differences of sound.

B. 2. The theory of Hutcheson differs very slightly from that usually ascribed to his distinguished contemporary Bishop Butler. According to this theory, man's actions are determined by various natural impulses and propensities, over which conscience is placed as the supreme and directing authority. Conscience is the faculty by which we discern the moral qualities of actions, and approve or disapprove them as such; and the authority assigned to it over the active faculties of our nature is its prerogative, secured to it by the Creator when he gave man his peculiar constitution. Were the power of conscience equal to its right, all our actions would be controlled by it; and were conscience itself always duly enlightened, our actions would be so controlled by it as to be always consistent with rectitude. "Acting, conduct, behaviour abstracted from all regard to what is in fact and event the consequence of it, is itself the natural object of the moral discernment, as speculative truth and falsehood is of speculative reason."³ "This moral discernment implies in the notion of it a rule of action, and a rule of a very peculiar kind; for it carries in it authority and a right of direction,—authority in such a sense as that we cannot depart from it without being self-condemned."⁴ "There is a principle of reflection in men by which they distinguish between, and approve and disapprove, their own actions. We are plainly constituted such sort of creatures as to reflect upon our own nature. The mind can take a view of what passes within itself, its propensions, aversions,
